Abbott, M., article by.....	178
— Rosa G., articles by.....	297, 337
Abelias, species of.....	267
Aberia Caffra.....	393
Abies amabilis.....	510
— Apollinis.....	511
— balsamea.....	510
— Cephalonica.....	511
— Cilicica.....	297, 511
— concolor.....	23, 510
— firma.....	510
— Fraseri.....	510
— grandis.....	29, 38, 510
— homolepis.....	510
— Hudsonica.....	510
— lasiocarpa.....	28, 53, 510
— magnifica.....	510, 517
— Mariesii.....	511
— nobilis.....	510, 517
— Nordmanniana.....	511
— Numidica.....	511
— pectinata.....	511
— Reginae-Amalie.....	511
— religiosa.....	510
— Sachalinensis.....	511
— Shastensis.....	184, 511
— Sibirica.....	23, 511
— the nomenclature of.....	239
— Veitchii.....	511
— venusta.....	510
— Webbiana.....	511
Adietene, the source of.....	202
Acacia armata hybrida.....	36
— longifolia.....	36
— species of.....	78, 156
Acanthopneux crinita.....	385
Acanthus latifolius.....	285
Acer glabrum.....	29, 379
— macrophyllum.....	39
— spicatum.....	115
Achimenes, cultivation of.....	346
Acrida australis.....	484
Aconitum autumnale.....	395
— uncinatum.....	346
Acorus Calamus.....	253
Actea spicata rubra.....	218
Adenostoma fascicularis.....	72, 83, 102
Adiantum Bessoniifolium.....	294
— emarginatum.....	146
— Farleyense, cultivation of.....	106, 317
— pedatum.....	146
Adirondacks, Governor Black's mes- sage on the.....	21
Adonis Amurensis.....	94
— vernalis.....	130, 177
Advertising nuisance, the.....	409
Agaricus campestris.....	469
Agave attenuata.....	95*
Agricultural Science, Society for the Promotion of.....	358
Agricultural education.....	61, 181, 270, 458
Agriculture, home reading course in.....	30, 518
— in Alaska, prospects of.....	263
Ailanthus in Utah.....	357
Ajuga reptans.....	207
Alaska, the agricultural prospects of.....	263
— the forests of.....	379
Alberta magna.....	24, 494
Aleyrodes vaporariorum.....	194*
Alligator pear, the.....	260
Allium vineale.....	120
Alnus rhombifolia.....	29
— tenuifolia.....	29
— tinctoria.....	472*
Alocasias, cultivation of.....	27
Alströmeria aurantiaca.....	284
Althea officinalis.....	273
— rosea.....	364
Amanita muscaria.....	469
Amaranthus retroflexus.....	239
Amaryllis, cultivation of.....	495
— hybrid for winter flowering.....	415
— in Massachusetts.....	190
Amelanchier alnifolia.....	28
— Canadensis.....	115

American Institute, meeting of Farmers Club.....	199, 250
— of New York, exhibi- tion of flowers, fruits and vegeta- bles.....	398, 468
Ampelopsis, the Japanese.....	96
Anacyclus Pyrethrum.....	273
Anchusa Barrelieri.....	216
Andrews, D. M., article by.....	98
Anemone Japonica alba.....	395, 415
— nemorosa Robinsoniana.....	190
— occidentalis.....	53
— Pulsatilla.....	177
— sylvestris.....	208
— umbellata.....	217
Angelica atropurpurea.....	273
Angræcum sesquipedale.....	78
Annals at Cornell University, tests of.....	158, 425
— some showy.....	374
Anoda acerifolia.....	346
Anoiganthus breviflorus.....	74
Anona Cherimolia.....	10
Antennaria Parlinii.....	284
Anthemis tinctoria.....	288
Antholyza Ethiopica.....	136
— crocosmoides.....	315
Anthraxnose of black raspberry.....	250
Anthuriums, cultivation of.....	27
Antirrhinum Oronotum.....	313
Antirrhinum, cultivation of.....	286, 355
Apera arundinacea.....	412, 428
Aphelandras, cultivation of.....	77
Apios tuberosa, edible character of tubers of.....	466
Apocynum cannabinum.....	273
Apple, Albemarle pippin.....	69
— grafting the.....	318
— growing in New Jersey.....	170
— rust of the.....	198
— the Jonathan.....	58, 99
Apples, American, in England.....	60
— Australian, diseased.....	210
— crab, flowers of.....	116, 189
— grafted.....	290
— in America.....	328
— insect pest of.....	50
— the thinning of.....	40, 68
Apricot, Early Montgamet.....	327
Aquatics, winter-flowering.....	67
Aquilegia, hybrid.....	216
Arabis albidia.....	177
Aralia papyrifera.....	16
— quiquefolia.....	253
Arbor-vite, species of.....	449, 441
Arbor-vites in Kansas.....	23
Arbutus Menziesii.....	29, 81
Arctostaphylos Uva-ursi.....	350
Arenia saccharifera.....	385
Arenia laterifolia.....	68
Aristolochia, a new hybrid.....	358
— Goldiana.....	223
Arizona, notes on the pine forests of.....	152
Arkansas, fruit-growing in.....	379
Arnold Arboretum, notes from the.....	226
Arundinaria Japonica.....	147
Arundo Donax.....	355
Asclepias, cruelty of.....	341
— Curassavica.....	414
— incarnata.....	336
— tuberosa.....	273
Ash, the Mountain.....	86*
Ashe, Prof. William Willard, article by.....	304
Ashes, quality of.....	150, 190
Asparagus rust.....	236, 335*
— Sprengeri.....	238, 248, 317
Asphodelus ramosus.....	277
Aspidiotus secretus on bamboos.....	418
Aspidium Felix-mas.....	273
— marginale.....	373
Aster alpinus.....	226
— junceus.....	64*
— pulchellus.....	53
— sericeus.....	415
— tardiflorus.....	14*
— turbinellus.....	415
Asters, cultivated.....	395
Astrapea Wallichii.....	255

Atkinson, George F., articles by.....	34, 73
Aubrietias.....	177
Audubon Society of Massachusetts.....	419
Auriculas in England.....	173
Autumn effects of shrubs and trees.....	417,
— 428, 436, 438, 447, 448, 468, 471, 472, 478	
— foliage.....	416
— fruits in the Pines.....	471
— protection of plants.....	475
— work among trees.....	429
Azalea Indica.....	128
— Kämpferi.....	226
— Vaseyi.....	468
Azaleas, cultivation of.....	150

## B

Baccharis halimifolia.....	136
Baden-Baden, notes from.....	57, 167,
— 277, 424	
Bailey, Prof. L. H., articles by.....	169,
— 248, 316, 321, 391	
— Veitch medal	
— awarded to.....	60
Baker, E. G., article by.....	244
Bamboos, diseased.....	418
— hardy, at Kew.....	378
— in Florida.....	147
Bambusa argentea.....	148
— arundinaria.....	148
— falcata.....	148
— Metake.....	147
— vulgaris.....	147
Baptisia perfoliata.....	257
Barber, John H., article by.....	341
Barley for port wine.....	190
Barry, address by President.....	58
Bassett, F. L., article by.....	68
Bateman, James, sketch of.....	508
Baxter, Sylvester, articles by.....	108, 466
Beach, Prof. S. A., article by.....	461
Beal, Prof. W. J., article by.....	365
Bean, the Soy.....	388
Beans, cultivation of.....	50, 358
— Lima, cultivation of.....	25, 358
Beautifying of a neglected field, the.....	466
Beddwith, W. H., article by.....	88
Bedding plants, cultivation of.....	156, 178
— stock, wintering.....	476
Beech, the American.....	116
Bees, their loads.....	448
Beet-sugar, manufacture of.....	348, 418
Beets, the cooking of.....	60
Begonia Ferdinand de Lesseps.....	118
— Gloire de Lorraine.....	16, 442, 4
— 8,	
— Lyncheana.....	114
— Mrs. Heal.....	494
— Rex.....	355
— semperflorens.....	114, 476
Begonias, bedding.....	593
— crested.....	353, 367, 442
— for planting out.....	178
— for winter flowering.....	355
— tuberous.....	374
— cultivation of.....	257
— winter-flowering.....	484
Bell, E. Hamilton, article by.....	252
Berberis Aquifolium.....	117, 197
— species of.....	227
— Thunbergii.....	478
Berteroa incana.....	260
Bertolonias, cultivation of.....	77
Bertonera.....	114
Bessey, Professor Charles E., article by.....	456
Betula Maximowiczii.....	21
— occidentalis.....	28
Birches, American.....	115
Birds, preservation of our native.....	419
Blackberries in North Carolina.....	230
Blackberry, the Mammoth.....	478
Bocconia cordata.....	307
Boltonia asteroideae.....	395
Border plants.....	306
Borders, perennial, autumn care of.....	486
Boronia, species of.....	36, 156, 214

Boston, flower exhibitions in.....	129,
— 229, 258, 447, 493	
— the park system of Greater.....	241
Botanic Garden of Smith College.....	512*
— notes	
— from.....	66, 117
— of the Michigan Agri- cultural College.....	365
Botany of some southern swamps, notes on the.....	514
Bougainvillea Sanderiana.....	16, 392
Bouvardia, treatment of old plants of.....	178
Bowenia spectabilis.....	224
Box Elder in Utah, the.....	357
— trees in Bartram Garden.....	498
Brachycome iberidifolia.....	316
Bradley, David E., article by.....	209
— William L., memorial to.....	312, 340
Brassicas, the cultivated.....	321
Brianthus empetrifolius.....	53
Britton, Prof. W. E., articles by.....	107,
— 194, 326, 450	
Brookline, Massachusetts, notes from.....	117
Browallia speciosa major.....	325
Brown-tail moth, the.....	281, 298
Brunfelsia latifolia.....	36
Buddleia variabilis.....	404
Bulb, definition of a.....	154
Bulbophyllum Dayanum.....	54
Bulbs, hardy, cultivation of, in Eng- land.....	150, 375, 415
— the storing of.....	445
Buphthalmum salicifolium.....	99
Burdock, economic value of.....	143, 253
Bush, B. F., article by.....	514
Butternut, insect enemy of.....	278
Books Reviewed:

Patton's Spruce.

BY the increasing number of travelers who explore the high mountains of the Pacific states, which are its only home, the lovely Mountain Hemlock is now usually known as Patton's Spruce. Perhaps best considered a Hemlock, this tree differs from other Hemlocks in its long, narrow cones and in its more acute leaves usually keeled on the upper surface, and its bilobed pollen grains; and in general appearance it is one of the most distinct and beautiful of the North American conifers.

Tsuga Pattoniana, as botanists call this tree, was discovered only about forty-five years ago near Mount Baker, in northern Washington, by the Scotch collector Jeffrey, and was named out of compliment to George Patton, a Scotch lawyer, who was given to the cultivation of exotic trees, and was one of the subscribers to the fund which enabled Jeffrey to explore the forests of north-western America.

Patton's Spruce is now known to range from Alaska, where it grows at the level of the sea, southward along the mountain ranges of British Columbia, west of the continental divide, the two slopes of the Cascade Mountains of Washington and Oregon and the California Sierra Nevada, where probably on the upper waters of some of the tributaries of King's River it finds its most southern home. It is a tree of high altitudes, and, except at the extreme north, it is found only near the timber-line, forming with Pinus albicaulis and Abies lasiocarpa extensive forests.

Patton's Spruce is a tree of marvelous grace, with drooping branches clothed with thickly clustered leaves, abundant elongated narrow cones, which hang on slender spray-like branchlets, and on some individuals are bright purple, and light yellow on others in the same grove. The foliage, too, differs in color, being on some trees dark green and on others light blue-green, a peculiarity which has led to some confusion of nomenclature, the blue-leaf form often appearing in gardens as Tsuga (or Abies) Hookeriana.

Patton's Spruce grows in the greatest perfection on the slopes below Crater Lake, in the Cascade Mountains of southern Oregon, forming here extensive and nearly pure forests, in which individual trees one hundred feet high, with stout massive stems five or six feet in diameter, are

abundant. Such a growth is probably not exceptional, and this tree is abundant and conspicuous at the timber-line of Mount Hood, Mount Ranier, and on the Selkirk and other mountains of British Columbia. On Mount Ranier, with Abies amabilis and Abies lasiocarpa, it forms a large part of the forest growth, growing above the banks of glaciers in great luxuriance. Some idea of the upper forest-belt on Ranier can be obtained from our illustrations in this issue; that on page 6 displays the snow-covered summit rising 8,000 feet above the timber-line, with scattered trees of Patton's Spruce on the slope in the foreground, and in the illustration on page 7 the trunks of this tree are displayed in more detail.

In Washington and Oregon Patton's Spruce grows at elevations of from 5,000 to 6,000 feet above the sea-level, but farther south the timber-line is carried higher, and John Muir, who describes this tree in his *Mountains of California* as the "most singularly beautiful of all the California conifers," found it growing on the Sierras up to 10,000 feet altitude; and on the edge of Lake Hollow, at an elevation of 9,200 feet, measured a trunk nineteen feet seven inches in circumference at four feet above the ground. "No other of our alpine conifers," he tells us, "so finely veils its strength. Its delicate branches yield to the mountain's gentlest breeze, yet it is strong to meet the wildest onsets of the gale—strong not in resistance, but in compliance, bowing snow-laden to the ground, gracefully accepting burial, month after month, in the darkness beneath the heavy mantle of winter. Every tree-lover is sure to regard it with special admiration. Apathetic miners, ever seeking only gain or gold, stop to gaze on first meeting it, and mutter to themselves 'That is a mighty pretty tree.' The deer love to lie down beneath its spreading branches; bright streams from the snow that is always near ripple through its groves, and Bryanthus spreads precious carpets in its shade. But the best words only hint its charms."

Introduced into Scotch plantations by its discoverer, Patton's Spruce has shown that it is fairly adaptable to altered climatic conditions, and it may now be seen in many European collections, and although it has not yet had sufficient time to attain maturity in cultivation, it is an ornamental tree of much promise in several European countries. Patton's Spruce, moreover, is one of the comparatively small number of the conifers of the Pacific states which thrive in the east, and although, like most alpine conifers, it grows extremely slowly at the sea-level, it has for several years withstood without injury the changeable winters and dry summers of the New England climate.

The Planting of Shrubberies.

IN furnishing small areas about modest country and suburban houses, and, indeed, for a great many other purposes in larger and more pretentious grounds, public and private, deciduous flowering shrubs are so effective in this climate that every one who wishes to plant intelligently should be familiar with their habits and with the proper way of disposing them. Of course, no place except the very smallest can dispense with trees, and in many places low-growing evergreens, especially the broad-leaved evergreens, can also be used with profit. But when we consider the beauty and variety of their flowers and foliage and fruit, and the mist of soft color which hovers about their twigs in winter, deciduous shrubs are, beyond all question, the most important element in planting small grounds. This does not mean that all shrub plantations are satisfactory, for individual plants can be dotted about a lawn in a way that is utterly meaningless. They can be used, however, so as to make a picture which has individuality and character, and in which every detail contributes distinctly to the general impression and helps to bring it out in a clear and well-defined way.

This is an art which requires study and practice, and a bulletin lately issued by Professor Bailey, of the Cornell

Experiment Station, entitled *Suggestions for the Planting of Shrubbery*, will be found useful to novices and to many who are not altogether without experience. This little pamphlet, which lays down many sound principles, illustrated in a helpful way by half-tone pictures, shows at the outset an example of the common or nursery type of planting, in which each tree and shrub is treated as a disconnected individual, and a contrasting one in which the same materials are massed about the borders of the same lawn so as to make a satisfying and consistent picture. The point emphasized is that the value of the shrubbery lies primarily in the effect of the mass, and not of the separate shrubs. Illustrations are given to show how effective a natural copse may be when it stretches across a vale on the further border of a meadow, which it makes more beautiful by the mystery of its boundary. Nature's irregular planting of this sort is always interesting because of its attractive sky-line and the wonderful play of light and shadow on the masses of foliage that advance in promontories or retreat in quiet bays, with the greensward flowing about and among them like the waters of a lake rippling along a picturesque shore. The beauty of such a boundary is not fully appreciated until we study examples of another kind, and it is emphasized in this pamphlet by the picture of shrubbery in a city lot where each plant is pruned to a definite form with its outline sharp and hard, a practice which is utterly destructive of the continuous flow of form and color which makes a natural copse so delightful. Nothing is gained by planting shrubs in masses unless the plants are allowed to mingle so that the attention is not arrested by individuals. After this principle is established it is logical to insist on the elementary rule that for small places there should be a central open space without sharply defined limits, but with a natural or apparently unstudied border; that any arrangement which gives a patchy effect should be avoided, and that shrubs should be eschewed which are only interesting for their curious forms or singular colors.

Now, what class of shrubs is the most desirable? Different persons will have various preferences, but the main point is to be sure that the bulk of the planting consists of hardy and vigorous species, and for this nothing better can be chosen than many of our native species. Every planter who has room for Roses will plant them somewhere, but the foliage and habits of garden Roses are not such as give them value in a shrub border, although some of the species, like the Japanese *Rosa rugosa*, have distinct merit in a mass. There is no fear that our wild shrubs will look common when transferred from the woods to the lawn, for they develop such beauty under cultivation that those alone who are well acquainted with them will recognize them as the natives of our roadsides and wood borders. Of course, no one can plant effectively unless he has an affectionate regard for the shrubs he uses, and any one who establishes intimate relations with nature has the tenderest feeling for the wild things that he finds struggling for life along brook-sides and in the corners of pasture lots. This is why our native shrubs are always good for homelike pictures, and although we may take some interest in the variegated foliage and the weeping habit of the sports which are for sale in the nurseries, the greatest satisfaction will come from a sympathetic use of our own wild shrubs.

We commend this little pamphlet to our readers, not so much for its specific directions as for its general temper and the foundation principles which it lays down. One cultural rule, however, we are glad to see insisted on. This rule is, that in making a shrub group the holes for the bushes should not be made in the sod, but the entire area should be deeply spaded and the shrubs set in thickly. If small shrubs are set closely, say, eighteen inches or two feet apart, there will be no danger of a display of bare earth, for the whole surface will be practically covered with a carpet of green the first year. Under this plan, too, the plants can be hoed, and this stirring of the soil will

cause a much stronger growth, while just as soon as the plants begin to crowd each other they can be lifted from what is practically a home-made nursery. In this way the planter has not only a shrub garden at once, but he has a reserve garden in which for several years he can find supplies of the very best material for use in other places. Professor Bailey says that the man who plants his shrubs in holes in the sward does not seriously mean to make any foliage-mass, and it is likely that he does not know the value of broad masses in artistic planting. Where large shrubs have open spaces between them, some low-growing, procumbent species, like the hardy *Vinca* or *Evonymus obovatus*, may be planted, but all this is another matter. The rule for continuous cultivating in shrub groups is sound in theory, and it has proved of great advantage in practice in many places.

#### An Outline of a Course in Horticulture.

THE first question which confronts every teacher of horticulture is: What shall be included in horticultural instruction? Shall the course be restricted to the so-called practical problems attending the propagation of fruits and vegetables, or shall it be made to include the wider field of landscape-gardening and plant-breeding, and the application of the laws of vegetable physiology? Shall we study the art of raising plants, or shall we consider the principles on which the art is founded?

For my own part, I should not regard with favor a course in horticulture which is restricted to the mechanical operations of the propagation and culture of plants. The student should know something of the origin, habits and relationships of plants, also of the causes of variation and the effects likely to be produced by the operations he may perform. In other words, he should know something about plants and their amelioration, as well as something about their cultivation. For this reason, as well as to train the powers of observation, thorough knowledge of systematic, structural and physiological botany should be at the foundation of every course in horticulture.

A knowledge of agricultural chemistry, of elementary physics and of soils is also essential, for reasons which are apparent, and this work should precede technical instruction in horticulture. Accepting this view, no course in horticulture should be offered before the junior year in our colleges.

Beginning with the junior year a twelve or sixteen weeks' course in pomology may well be introduced. The student will at this time have had sufficient training in botany to understand the necessary discussions of the distinguishing characters and the relationships of the fruits studied, while the season is favorable for a field study of orchard fruits and grapes, with special reference to harvesting and marketing. The propagation and culture of many kinds of fruits may also be studied in a practical way at this time. In some sections the season will be too far advanced for budding, but the making of hardwood cuttings, and the pruning and preparing of plants for winter, afford abundant opportunity for illustration during the whole term. The subject of pomology is naturally treated under three sub-heads, viticulture, small-fruit culture and orchard culture. In some sections a fourth—nut culture—might well be added. Certain general principles may be stated which will hold in each of the divisions of the subject; then the various fruits included in each may be treated specifically. The scheme adopted in my own work is similar to that of Bailey, at Cornell, and is somewhat as follows: (1) Botanical; (2) History; (3) Importance and extent of cultivation; (4) Culture and management; (5) Harvesting, storing and marketing; (6) Propagation.

The winter term may profitably be devoted to greenhouse construction and management. This course should include a careful discussion of the evolution of the modern greenhouse and of the uses and details of construction of

the various forms of forcing structures. The physics of greenhouse roofs and the principles involved in the various methods of heating, as well as the mechanical operations of building and putting in heating and ventilating apparatus, should receive most careful attention. So far as practicable it has been found advantageous for students to visit commercial houses in the vicinity in order to make intelligent comparisons of the different methods employed. Practice in making designs and estimates for the construction of different styles of houses is of special importance in this connection.

In discussing the management of the houses, watering, ventilating, etc., the student's knowledge of physiological botany will be of practical value.

The spring is preëminently the time to take up the subject of vegetable gardening. Remarks concerning preliminary work for the course in pomology will apply to this course. In other words, a knowledge of botany, of soils, of drainage and of agricultural chemistry should precede the discussion of vegetable gardening. The general treatment of the subject at the Maine State College is somewhat similar to that outlined for the course in pomology. After some general notes on market gardening as a business and the extent of the industry, the leading garden vegetables are taken up in detail. As in the case of fruits, the vegetables naturally fall into several groups; root crops, or those in which roots or underground stems are edible; Cabbage-plants, the Solanums, the Cucurbits, the Alliums, etc. In studying the different groups the general characteristics are first given, together with a discussion of the distribution and relative importance of the various members. Then each species is treated in detail in the manner described for fruits. In this way the student gets a broader conception of the subject than is possible if no system be followed.

In the laboratory work which forms a part of this course, the student is made familiar with the different kinds of garden seeds, with methods of seed-testing, with soils and garden implements, as well as with the practical operations of planting, cultivating and marketing. The later operations may best be learned in detail when the student can devote his whole time to the work.

It is questionable whether, in the regular college course, more than one term may profitably be devoted to ornamental gardening. The leading object of such a course should be to arouse enthusiasm and a love for tasteful surroundings, with some ideas of the principles of taste, rather than to impart specific directions for the culture of certain species of plants. Naturally, the course should include directions as to the sources of information, and should, so far as possible, include practical demonstrations of the methods employed in managing different classes of plants. But, as a large majority of the students will be interested in this work only incidentally, it would seem that sixteen weeks is sufficient time for both landscape-gardening and floriculture. Here, however, as in all cases, local conditions must govern the policy adopted.

I should not regard the course as complete unless at least one term were devoted to a systematic study of plant-breeding. This study would properly include a consideration of the origin and distribution of cultivated plants; their variation as effected by soil, climate and cultivation; the influence of heredity, the principles of selection, the methods and effects of crossing, etc. In such a course the student may obtain some idea of the possibilities in the direction of scientific horticulture.

The remaining term of the senior year may profitably be spent in the investigation of special problems and in a study of horticultural literature. This course, as also the one in plant-breeding, would naturally be made elective. Laboratory work and collateral reading should be made important features of every course in horticulture, as it is a well-recognized fact that the student retains more lasting impressions from demonstrations than from the most carefully prepared lectures. The laboratory work should, how-

ever, be accompanied by informal discussions as thoroughly systematized as the class-room instruction, and, as far as possible, should follow the same lines as those taken up in the lectures.

The foregoing notes are intended to invite discussion concerning the purpose and scope of horticultural instruction, as well as methods of teaching, rather than as a contribution of special significance. In brief, however, my ideas on the subject are here given.

Maine State College.

### Three Natural Parks.

THE cities of Halifax, Truro and St. John, in the maritime provinces of Canada, are the possessors of parks of great natural beauty, each typical of the bold and rugged scenery which prevails on the adjacent coasts, and each one almost in its natural state. Point Pleasant Park, the oldest of the three, and formerly called Tower Woods, is on a point of land at the lower extremity of the magnificent harbor, stretching along the water-front and looking out upon the Atlantic Ocean. It occupies the entire southern end of the peninsula on which Halifax is built, and extends from the harbor on the one side to the Northwest Arm, and comprises about 180 acres, the highest point being some 150 feet above the sea. Except for the eight miles of road built through it, and many delightful foot-paths, it is entirely covered with forest. The property belongs to the Imperial Government, but the city has a perpetual lease and free use of it on the conditions that no buildings are to be put on it, and no wharves or traffic allowed on its shores, while the forts, of which there are several, are to remain under the control of the Imperial Government. The park is in charge of twelve commissioners appointed by the City Council, five of whom are permanent, the others being the Mayor and six Aldermen, who hold the position until their terms in the City Council expire. The city appropriates the modest sum of \$2,500 a year for the maintenance of the park. Of course, the commissioners are not paid, but the chairman devotes much of his time to the park as a labor of love. The main effort is to keep it essentially in forest and preserve its natural features. When the park was first begun, Prince Edward, the father of Queen Victoria, did much to beautify it, and his example has been followed by other distinguished commanders at Halifax since his time. The excellent roads are made chiefly by the soldiers. Except the fine iron gates at the entrance of the park, which, with considerable money to open the avenue to it, were a gift from the late Sir William Young, and a handsome keeper's lodge, in the course of erection, there is very little artificial work in this oldest of the parks of Canada. It is practically a magnificent grove of trees, making a typical forest of eastern Canada. During the last few years the commissioners have set out many young exotic trees and shrubs, but the native species have been so well preserved and kept in such prominence that the visitor finds it difficult to believe that he is not in a well-preserved natural forest. The fine Public Gardens of Halifax are not a part of the park, but are managed by a separate board.

The Victoria Park, at Truro, Nova Scotia, was founded about ten years ago, in the Queen's Jubilee year. Its situation and surroundings are romantic in the extreme. From a plateau at the top of a range of hills on the southern side of the city a stream flows down in a succession of cascades, forming a ravine which extends almost to the city limits. The stream finds its way through this ravine, now bounding over rocky ledges, now dimpling in foamy pools, until it enters a little glen, bordered with evergreen trees, about a quarter of a mile from the city. Here is the entrance to the park, rather sombre even on a bright October day, but when once the visitor enters the gorge the romantic beauty of the scene is one well fitted to captivate him. A path follows the windings of the stream for some distance, giving new views of picturesque scenery at every turn. Here a bare wall of red sandstone towers above the path for

nearly a hundred feet. On the opposite sides of the chasm the wall of rock is broken, and from the crevices are seen hanging in rich profusion such Ferns as Woodsias, Polypodium and Aspidiums, far beyond the reach of human hands. Here and there is some little dell, through which bubbles a miniature stream, its rocky banks covered with Mosses and Lichens. The largest of the falls has been named the Joe Howe Falls; it is about thirty or forty feet in height. On the bluff near by, it is proposed to erect a monument to the distinguished Nova Scotian after whom it is named; but it is to be hoped that the projectors will change their minds and either erect the monument near the entrance to the park or in the city. Any work of ornamentation in such a picturesque place would certainly be a blot. On the plateau, 200 feet above the ravine, a carriage-road extends, encircling the outer edge of the park, and numberless bypaths extend from this to points of vantage on the crags overlooking waterfalls, where on a bright October afternoon the visitor looks down on a scene of marvelous beauty, the gorgeous tints of Maples, Viburnums and Heaths darkened now by the sombre hue of evergreens, now lightened by the foam of waterfalls.

Mount Pleasant Park, at St. John, New Brunswick, situated near the city, has not yet been formally opened. It consists of 240 acres of land, some of which has been given by liberal citizens, some acquired by purchase, and some will come by expropriation. During the past two years the members of the Horticultural Association have endeavored in every possible way to interest citizens in the park scheme by planting the squares of the city with trees and flowers, and by holding exhibitions. When they have secured enough land for the park and have paid for it, the association proposes to hand it over to the city as a gift. It is hoped that the liberality and public spirit of these citizens will meet with a generous response on the part of the city government. The park site is a broken and picturesque plateau overlooking the city, intersected with ravines. A lake lies at its western extremity, from the eastern end of which a small stream finds its way over a succession of perpendicular rocks to the meadow below—forming a series of beautiful cascades about eighty feet in height. The most of the park lands so far acquired consist mainly of rocky hills and mounds covered with a growth of small shrubs, with stunted Spruces, Firs, White Birches, Maples and Cedars. The Cedars are shapely and beautiful, and if carefully handled will become one of the most beautiful ornaments of the park, the limestone formation being well adapted for their symmetrical growth. A roadway has been constructed around the lake, and it is hoped that the services of a competent landscape-gardener may be secured before anything more is undertaken. It would be a pity to go on blindly without a completed design, and a design which respects the peculiar charm of the place and which preserves and enhances it. A special feature of the park at this season is the native shrubbery which covers the rocks, and which yields the most brilliant and varied colors—stunted Vacciniums with their purple hues covering the rocks in every direction; several species of Viburnum, with their white and blue fruits in pleasing contrast, *Kalmia angustifolia*, *Rhododendron Rhodora*, *Sedum latifolium*, *Pyrus nigra*, and many others.

St. John, N. B.

### Plant Notes.

#### The Lilies of our Pacific Coast.

THE Pacific coast of the United States is wonderfully rich in members of the Lily family. With nearly forty *Calochorti*, over twenty *Brodiaëas* and thirty *Alliums*, nine *Fritillarias* and ten *Erythroniums*, as many or more *Liliums*, and fifty other species distributed among twenty-five genera, the *Liliaceæ* of the Pacific slope include a grand total of over one hundred and seventy species, in a vast and comparatively unknown region, the exploration of which annually adds new species or proves the existence

of forms described by the earlier botanists and since lost sight of. I doubt if there is any other region in the world where the Lily family is so rich and varied.

The number of *Liliums* or true Lilies on the Coast varies according to the nomenclature followed. *The Botany of California*, published in 1880, mentions eight species and one variety. Mr. Baker more correctly, as I think, distributes the same material into fifteen species and varieties in his synopsis of the genus. These species can be divided into several groups according to their natural affinities. *Lilium Washingtonianum* and its varieties, with the nearly related *L. rubescens*, will form the first of these groups, and into the second will naturally fall *L. Columbianum*, *L. Humboldtii* and its varieties, and *L. Bloomerianum*, which is also known as *L. Humboldtii*, var. *ocellatum*. *L. Bolanderi*, too, shares in the solid ovoid bulb and leaf character of this group, although its flowers differ in form.

A third group, and a very large one it is, will contain the western relatives of *Lilium superbum*, large bog Lilies with rhizomatous roots and revolute flowers. These are *L. pardalinum*, *L. Roezlii* and *L. Warei*, with the innumerable forms of *L. pardalinum*, some of which, as *L. Californicum*, *L. Bourgæi* and *L. puberulum*, are often treated as species. This wonderfully varied group is connected by a close chain of intermediate forms, possibly crosses, with the next group, which consists of the western relatives of *L. Canadense*. In this group of small-flowered bog Lilies, *L. parvum* is nearly as various in its forms as is *L. pardalinum*, but *L. maritimum* is, as far as my observation goes, strictly monotypic. The type of *L. parvum* and *L. maritimum* have funnel-formed flowers.

*Lilium Parryi* is closely related to the *Pardalinum* group, differing only in having trumpet-shaped flowers. In growth it can hardly be distinguished from *L. pardalinum*.

Of these eleven species, *Lilium pardalinum* is most widely distributed, being scattered from central California to British Columbia, and eastwardly to the shores of Lake Winnipeg. *L. Washingtonianum* inhabits a long and narrow belt in the main Sierra Nevada range and in the Cascades to British America. *L. Parryi* is found in Arizona as well as in its original location in southern California, and *L. Columbianum* is found to extend far east of the Cascades in the Columbia River valley, but with these exceptions these Lilies belong to the mountainous regions of the Pacific Coast proper in the Sierra Nevada and Coast ranges. I have already written of *L. Washingtonianum* and its varieties (vol. ix., p. 448), and of *L. rubescens* (vol. ix., p. 493). In an early issue I hope to write of *L. Humboldtii* and its allies.

### Cultural Department.

#### Notes on Cyripediums.

AT no period of the year is a good collection of *Cyripediums* entirely flowerless, but during the winter months when the temperature of the greenhouse is congenial they flower bountifully and their prolonged period of bloom gives opportunities for study and close acquaintance. It has been urged by some that Orchids out of flower are the reverse of ornamental, and this is true of some genera. *Cyripediums*, however, are rich in luxuriant leaf-growth, and not a few of them are worthy of cultivation for this feature alone, the deep green leaves being exquisitely marbled and variegated. Their growing popularity is attested by the fact that some of the more common species, like *C. insigne*, furnish cut flowers by the thousand for the New York market. To the amateur a little house of *Cyripediums* will give hours of infinite pleasure in winter, and hundreds of plants can be accommodated in a modest structure. The original wild species from many lands would of themselves furnish a rich store, but the hybrids of the last decade alone have here given us additional forms and colors in almost infinite variety. In fact, the hybrids are the majority among *Cyripediums*, and there is an endless fund of delight in comparing them, observing traits so plainly inherited that the parentage of many plants can be absolutely vouched for.

*Cyripedium insigne* is the type of quite an extensive family,

of which many members show marked improvements on the original. It is a native of Nepal, introduced early in the century, and now has over forty named varieties. One of the finest of these forms which we now have in flower is *C. insigne* Colsonianum, sent out from the Short Hills nursery. The very large dorsal sepal is the feature of the flower, the breadth and purity of its white margin being especially noticeable; in fact, nearly one-half of it is of this color, the base having the characteristic apple-green tint with prominent brown spots, the petals gracefully undulated, with the abundant spots disposed in a regular horizontal alignment. Of quite a different type is the dwarf variety *Eyermaunianum*. Its dorsal sepal is of a transparent greenish-yellow tipped with white, the petals and pouch also pale, unspotted, faintly lined, but the staminode is of a conspicuously rich yellow hue. *C. nitens*, a hybrid between parents *C. insigne* Maulei and *C. villosum*, is handsome and blooms freely. Its bold chocolate-spotted dorsal sepal shows the blood of *C. Maulei*; light brownish yellow petals, glistening like those of its other parent, are faintly lined with brown, infolding toward the polished light brown lip. Forms of the well-known hybrid *C. Leeaunum* are now numerous and most interesting. The characteristics of *C. Spicerianum* predominates in all these forms so much that there is little apparent trace of *C. insigne* Maulei, or the other parent *C. Maulei*. The best of the several forms we have is that known as *Masureelianum*, which was also sent out from the Short Hills nursery, and now has several fine flowers open. Its dorsal sepal is very large and of elegant curvature, recurving at the base till the edges overlap, and looking at the dorsal sepal from behind it is in shape a perfect miniature of the Arum Lily, in pure white. In front it is marked with broken lines and dots of light purple, but there is a broad margin of purest white. The *insigne* influence is apparent in the petals which, gracefully undulated along their edges, are brownish yellow, spotted with a darker brown pouch of a similar hue, but its inner surface pitted with innumerable tiny red dots. Other good forms of *C. Leeaunum* in flower are *Giganteum*, *Burfordense* and *Superbum*, all sufficiently distinct to justify their varietal names, while *Pulchellum* is quite a little gem with a neat flower, the dorsal sepal much contracted, green tinged and lightly spotted, the petals narrow and decidedly drooping, the pouch short, with a widely expanded aperture, while the staminode differs in color from the previous named forms and attracts notice in consequence by reason of its exquisite mauve color, the yellow protuberance in its centre standing out in rich contrast.

*Cypripedium macropterum*, a Veitchian production, is a hybrid between *C. Lowi* and *C. superbiens*. We have a noble scape of this, carrying two fine flowers and a bud yet to expand. The open flowers with their long horizontally poised petals measure nearly six inches across. The dorsal sepal is of a quaint shade of gray-green, lined and suffused with brown at its base. The petals are long, making a flower of graceful outline, as they depend somewhat at their tips, describing quite a semicircle. They are somewhat narrow at the base of attachment, but broaden toward their extremities, the broader half being of a light glistening, uniform mauve-purple, while the anterior portions are heavily dotted with shining black spots. The pouch is light brown. *C. Harrisianum* is as well adapted to grow in quantity for cutting as *C. insigne*, while some of its forms are highly conspicuous, as, for example, *Superbum*, a truly superb form in every respect. This has a very large dorsal sepal of exquisite coloring, a kind of mahogany-red in vertical lines running up the sepal over a lighter shade of purple-red diffused through the sepal, save a well-defined narrow margin of white. The petals are a rich purple-red in the upper half, but the lower portions much paler-tinted and faintly lined with green. The lip is prominent, of a claret-purple shading toward green at its tip. The variety *Pitcherianum* shows distinctive traits compared with its immediate relative.

*Cypripedium Lawrenceanum*, a Bornean species discovered by Burbidge in 1878, is a noble *Cypripedium*, as beautiful in leaf as in flower. It is represented in our collection by a very fine form, indeed, named *Giganteum*. Though a small plant, it carries an immense flower on a stout stem over one foot high. Its dorsal sepal is a study of rich coloring. Mainly white, it shades to light green at the base, while broad vertical lines of claret-purple of varying length streak the sepal, and their color is faintly diffused through the white body-ground. The petals are light green, ciliated along their edges, while half a dozen black spots are distributed along the upper and lower borders of both petals. The pouch is large, of a light brownish green, pitted inside with dark purple dots. *C. Niobe* Shorthillense flowers with great freedom, a plant in a three-inch pot carrying six perfect flowers. The influence of one of its parents, *C. Spicerianum*, is most marked in the dorsal sepal,

which is white, heavily lined and suffused with purple, the base of the sepal a brownish green. The petals have the graceful undulations and show characteristics of its other parent, *C. Fairreanum*. They are lined and suffused with chocolate on a greenish yellow ground, the short pouch glistening as though polished, being of the same tone of color. Another dainty gem of *Spicerianum* parentage is *C. Hebe*, which was raised at Short Hills; a tiny plant has two perfect flowers. It has a broad dorsal sepal, mainly white, but with a distinct band of purple right down the centre, and a few spots and suffusions of the same tint on the white ground color. It has short, narrow, wavy petals spotted with brown on greenish yellow, a short, broad pouch with infolding lobes, externally light chocolate, internally profusely red-spotted. *C. Arthurianum* is a lovely hybrid with *C. insigne* and *C. Fairreanum* for its parents. It is a dwarf grower, neat and free in flowering, its dorsal sepal bright green, tipped with pure white and penciled with brown in broken lines. Its wavy, drooping petals impart to the flower a graceful expression. They are lined and spotted with brown, the pouch also similarly tinted. Other *Cypripediums* of interest also in flower are *C. concinnum* transparens, quaintly colored in rosy purple and white, with a peculiar transparent lustre; *C. regale*, of marked distinctness, noteworthy for its clean-cut, regular form, its dorsal sepal tipped with white and streaked with dark olive-green, petals and pouch colored in a pretty harmony of brown and green; *C. luridum* in two forms; *C. Mrs. Edward Warren Hook*, with a polished purple-red flower of bright and attractive coloring, and *C. Tonso-villosum*, a comparatively colorless hybrid with fine flowers in subdued tones of brown, green and yellow.

A. Herrington.

### Nepenthes.

PITCHER-PLANTS are for the most part more interesting than showy. The flowers being inconspicuous, their chief beauty is in what is commonly called the pitchers. The genus comprises a considerable number of species and varieties, and the form or color of the pitchers constitutes the chief distinction, though they vary considerably in size, texture of leaf and vigor of growth. They are generally considered plants of easy culture, but this greatly depends upon the facilities. It is almost useless to attempt to grow them in an unsuitable house or in one in which the proper atmospheric conditions cannot be maintained. They require abundant atmospheric moisture at all times, but fresh air is also necessary. I have seen them grown in a house with a northern elevation, but one with a southern elevation is preferable, though, of course, it will require slightly more shade. This shading should in no case be overdone, for, in our experience, they have stood a greater amount of light than is usually allowed. It is only necessary to break off the strong sun rays, and for this purpose light muslin or cheesecloth is useful. The usual means of propagation is by cuttings. Several methods of striking are adopted, but the simplest and most convenient is to firmly insert the cuttings made from well-ripened one-year growths, singly, in small pots filled with sharp clean sand. These are plunged in a propagating-case where a good bottom-heat can be maintained, and kept liberally sprinkled with water heated to the same temperature as that of the case. We make the cuttings from single joints, with leaf attached, cutting from one to two inches below and one inch above the leaf. The longest of the leaves are sometimes shortened to save space, but otherwise this is not necessary. After striking, the first shift is made into three-inch pots; the principal material used is fibrous peat, with a surface covering of sphagnum-moss, and the whole should be firmly packed in the pots or baskets. We prefer to plant in baskets after the plants have attained sufficient size. The moss on the surface helps to retain the moisture, for lack of which they should never be allowed to suffer. If plenty of water is not given, the pitchers will become shriveled at an early stage of their formation, and the leaves will lose their bright green color and assume a reddish tint. During the summer months syringing will be required three or four times a day. In winter less syringing will answer, but hard firing will necessitate the frequent application of water to the pathways and brickwork of the house to guard against a drying atmosphere. This syringing and damping also serves to keep down red spider, the most dreaded insect enemy. We try to maintain a night temperature of about sixty-five degrees during the winter months, allowing a rise of about ten degrees by day. For the summer months, of course, it is impossible to lay down a hard and fast rule. As *Nepenthes* grow rapidly we find it desirable to shorten back or cut them down every season. They break very readily. If allowed to run they incline to produce flowers

rather than pitchers. A few may be allowed to flower and ripen their seeds if it is intended to raise young plants by this means. Hand pollination is necessary, as the male and female flowers are produced on different spikes, and in some cases on different plants. The variety *N. Veitchii*, for example, usually produces female, while *N. lanata* generally throws

post of chopped sphagnum and peat, with a little sand. A good percentage of the seed will germinate, providing it has been well ripened, but in a minimum temperature of sixty-five degrees it will take from two to three months. When large enough the plants should be set singly into smallest size pots, using the same compost as for sowing the seed. The pots

Fig. 1.—Patton's Spruce, *Tsuga Pattoniana*, on Mount Ranier.—See page 1.

male flowers, though this should not be taken as a hard and fast rule. The seed takes several months to ripen, so that the work is somewhat slow, though none the less interesting. When nearing the ripening stage a close watch should be kept or the pods may burst and the seeds drop out. The seeds should be sown in pans as soon as gathered, in a com-

post of chopped sphagnum and peat, with a little sand. It is a good plan to plunge them in pans or boxes, as they can then be readily shifted about, and it is thus easy to place them in a lighter situation. Additional shiftings must be attended to when required. The raising of these seedlings requires considerable patience, as it takes about three years of careful watching before the result

of the labor is shown, and another year before it is certainly determined. A great majority of the seedlings usually turn out well, however, and, strange to say, scarcely any two are alike, a fact which accounts largely for the numerous varieties found in cultivation.

Tarrytown, N. Y.

*William Scott.*

for outdoor decoration is the variegated *Arundo donax*, and this is a good time to prepare for its increase. One of the most satisfactory ways of working up a stock is by treating the canes of last season's growth just as *Dracæna* canes are handled—that is, by laying them down in a propagating bed and just covering them with sand or a mixture of sand and

Fig. 2.—Patton's Spruce on Mount Ranier.—See page 1.

#### Hints on Propagation.

**M**ANY plants are quite readily propagated during the winter, more easily, in fact, than in spring, when the sun is stronger, and the vitality of cuttings is quickly exhausted unless they are carefully watched. Among the useful plants

sphagnum, or sand and cocoa fibre. If kept thoroughly moist, these canes will break from nearly every joint, and the young shoots will emit roots and may then be cut from the parent cane and potted up. The same result is sometimes secured when these canes are placed in a tank of water in a warm house, and I have seen an excellent crop of young plants

raised from canes that were laid in a shallow pond outdoors in the summer.

*Pandanus Veitchii* roots now, and a point worth remembering about *Pandanus* cuttings in general is, that they root more quickly when kept a little on the side of dryness and only have water enough to prevent shriveling. This rule also applies to cuttings of variegated Pineapple and to various other Bromeliads.

The reference to *Dracaena* canes suggests the hint that nice top cuttings of these plants can usually be rooted without loss of foliage by nicking the stem with a sharp knife and then mossaing up the wound, imitating the treatment often given to *Ficus elastica*. Strong, brightly colored *Croton* tops may be managed to advantage in the same way. To have finely colored *Crotons* it is wiser to select the cuttings to some extent, for while some varieties seem to color up well without special selection, yet there are others that cannot be relied on unless the cuttings are well-marked growths. With both *Dracaenas* and *Crotons* the best results are obtained from strong young plants that have not been stunted in any way, but grown on rapidly by good feeding.

*Fatsia papyrifera* and *F. Japonica*, both of which are useful in the conservatory and in the outdoor garden, may be increased by means of short sections of the stronger roots, buried to a depth of half an inch in sand or light soil in a moderately warm greenhouse. These plants also come freely from seeds, but where the stock is small the roots are more readily obtainable. Root-cuttings, too, offer a practical way to propagate some of the *Clerodendrons* and *Bignonias*, for by this means a stock may be obtained with less trouble than by top cuttings. Cuttings of *Roses*, and of *Tea Roses* particularly, are just now in order, and the wisdom of a proper selection of good healthy growth for this purpose will be apparent to every one who makes the experiment.

If suitable roots of *Clematis flammula* or *C. Vitalba* are at hand they may now be used for stocks on which to graft some of the finer varieties, and a little work of this character will furnish a pleasant variety in the routine of the season. The roots used for this purpose should be stout, clean and free from bruises, and the scions made from firm clean wood. Cleft-grafting is the most convenient method. After grafting, the plants should be buried in sand in slight bottom-heat until the union has taken place, after which they may be potted up into small pots.

Holmesburg, Pa.

W. H. Taplin.

### Climbing Plants for Indoor Decoration.

ONE of the very best of this class of plants to train about a window is *Maurandia Barclayana*, a native of Mexico, with showy blue or purple flowers shaped like those of an *Antirrhinum*, although the tube of the corolla is not enlarged at the base and the so-called palate is not so prominent. These plants are easily grown from seed and can be lifted from the open ground early in autumn, or they can be planted in good-sized pots and sunk out-of-doors during the summer. They are easily supported on cords, about which they twist their petioles, and they have delicate hastate leaves which are most attractive. They bloom abundantly all winter long.

Another good plant is *Cobaea scandens*, which has pinnate leaves with tendrils and large greenish-purple flowers, which are bell-shaped and very abundant. It can also be grown from seed and treated like an annual. It grows very rapidly and can be carried away from the light along the ceiling of a room, and in this position, out of the direct sunshine, the flowers are bleached white and very interesting. *Solanum jasminoides* is another admirable plant for this purpose, producing clusters of pure white flowers, which in the variety known as *grandiflorum* are an inch across. This plant will grow out-of-doors in the summer-time perfectly well, and there is no better one for the decoration of verandas at that season, or of windows in the winter, as it seems to endure the dry heat of a house much better than most others. It belongs to the same family as the Potato, as any one can see by a single glance at its flowers. It was introduced from South America more than fifty years ago, and recently it has become quite common. *Manettia bicolor* is another good plant of this sort, with lance-shaped leaves and flowers with tubes of bright scarlet and yellow segments. A good annual plant is *Thunbergia alata*, which can be propagated from seeds like the *Maurandia*. It has white or buff-colored, salver-shaped flowers, often with a dark throat. The Butterfly Vine, *Stigmaphyllon*, with heart-shaped leaves and bright yellow flowers, is rather harder to manage than the others, but it is a beautiful plant for sunny places, and it flowers abundantly in small pots. It is a graceful plant with

slender stems. The Ivy-leaved *Geranium* has a rich glossy foliage and clustered flowers of a great many colors. It is as easy to grow as the common *Geranium*, and can be trained on cords, but it is better to droop around the edges of the vase or from a hanging basket.

## Correspondence.

### Dendrolene.

To the Editor of GARDEN AND FOREST:

Sir,—The communication from Mr. Troop, in the number of GARDEN AND FOREST for December 2d, requires a statement from me.

In Bulletin III of the New Jersey Experiment Station, I gave the results of a season's test of "Raupenleim" and "Dendrolene." Raupenleim, an old German preparation, is too expensive in the United States to be of practical value to our farmers, and the effort was made to obtain a native substance that would answer the same purposes at less cost. Professor F. L. Nason, to whom I suggested the matter, thought he could get a material that would answer as well and would be essentially the same as the European product.

Professor Nason was not then and never has been connected with the New Jersey Experiment Stations, and the Dendrolene was not in any sense the result of any investigations made by the Station, nor are we responsible for the statements of any advertisement. The results of my experiments, as given in GARDEN AND FOREST, were exceedingly satisfactory, and those results were accurately stated. Up to the time of publication of my annual report for 1895 no injurious effects were observed on any of the trees under observation in New Jersey. It is to be noted, however, that in my record of experiments only two young trees were treated. On page 10 of Bulletin III, the condition of these trees on September 3d is noted, and it is stated that the European material was the one employed on them. The effect of the material on very young trees, therefore, was not a matter of direct or special experiment. It is certain that none of the older bearing trees in the Durand orchard were in any way injured by the material applied. Early in the present year (March or April), the Messrs. Durand informed me that the two young trees which were coated the entire season of 1895 were still healthy.

On the White orchard of Peach-trees, where the material was applied to keep out the Peach borer, and where hundreds of trees were treated, so sign of any injury was to be seen at the time my bulletin went to press. In the spring of 1896 it was found that there had been considerable penetration through the thin bark of the youngest trees and an apparent check in growth. The injury did not extend to the inner bark, but was taken as a caution and no new coating was applied. It was found, on examination, that the Dendrolene had gradually penetrated the bark tissue of the younger trees, killing the cells as far as it went, and, of course, interfering with the proper circulation of the sap. In the most extreme cases there was a perceptible constriction of the trunk, as if made by a tight band; but this was only found on a few of the youngest trees, not yet in bearing. On the larger Peach-trees no harm resulted, and apparently the material did not get through the dry and hard outer tissue. The Bowker Company was notified of these facts before the beginning of May, and was requested to caution purchasers of their material on these points—especially those intending to use it on Peach-trees, and to discourage a continuous application in any case. It was intended during the season of 1896 to make a thorough test of Dendrolene, mixed with a variety of substances that would reduce its penetrating power, but the experiments were not carried out, on account of my absence.

Dendrolene, so far as I know, contains no caustic and no acid. It is absolutely neutral to all ordinary tests, and the injuries, so far as any have been caused by it, are due to the fact that it very gradually penetrates into thin, active, growing tissue, especially where it gains nutriment of any kind from without. In no case was fully matured outer bark penetrated by the material; only the very young, growing tissue. Furthermore, so far as my observation extended, the penetration is extremely slow, not being noticeable on the young Peach-trees until almost a year from the date of the application. I am yet confident that the material is a good one and that it will serve a useful purpose, though more widely different than I had supposed from the Raupenleim. It will require, however, much more experiment before its true place is ascertained, and its range of usefulness will probably be much more restricted than I hoped at first, and believed. At all events, it will be

well to exercise care in applying the material on young trees, and I would not now advise any application to remain permanently.

Rutgers College.

## Recent Publications.

*The Timber Pines of the Southern United States.* By Charles Mohr, Ph. D. Together with a Discussion of the Structure of their Wood. By Filibert Roth. Washington: Government Printing Office.

These monographs have been prepared under the direction of Mr. B. E. Fernow, Chief of the Division of Forestry of the United States Department of Agriculture, for the purpose of giving a true conception of the "extent, condition and value of the pineries of the south and of the nature, development and characteristics (botanical, silvicultural and technological) of the Pines in that region, with the hope of inducing natural forestry methods in their use and reproduction." This purpose has been well carried out, and the bulletin will take rank among the most instructive publications of the department.

Dr. Mohr's part of the work consists of about a hundred quarto pages, and since he has been a frequent contributor to these columns our readers need not be told how thoroughly he has studied these interesting forests, and how clearly and how carefully he has treated the subject from both scientific and economical points of view. Of course, the greatest part of his work is devoted to the Long-leaved Pine, *Pinus palustris*, the great timber-tree of the south, which is found in the maritime belt about 125 miles wide, sweeping along the coasts of the Atlantic and Gulf from the southern boundary of Virginia to the uplands which border on the Mississippi River bottom. The wood of this Pine is unsurpassed by that of any other conifer for purposes of construction, and equal to that of almost any timber-tree in economical importance, so that it has always been in great demand for naval architecture, for civil engineering and for all purposes of heavy construction. Both for home use and for export it has been recklessly cut, while the manufacture of naval stores from its resin is one of the most largely developed industries of the southern states, as well as one of the most wasteful industries now prosecuted by civilized man. Investigations by the Division of Forestry have shown that the boxing of a tree does not injure the strength or durability of its heart-wood, but if the tree is left standing, the wound, of course, interferes with healthy growth, while beetles bore their way into its trunk, and spores of fungi find entrance to cause decay. Worse still, the exuded resin so increases the inflammability of the woods that a fire once started soon sweeps over a large area, not only destroying the standing timber, but excluding all hope of new growth. The first plate in this volume, which shows a stretch of this Pine land after the merchantable timber has been removed, presents a scene familiar to every traveler in the coast region. The trees are spindling, scattered, blackened by fire, and this desolated forest makes one of the most depressing landscapes that can be imagined. Throughout the area of nearly a hundred thousand square miles over which the Long-leaved Pine extends, a stupendous amount of timber-wealth still remains, in spite of the immense amount of land that has been cleared for agricultural purposes, and the large sections from which the good timber has been culled out or the original growth entirely destroyed. But when we remember that the present annual cut will increase as the northern Pine gives out, it is clear that the logger is far outstripping the possibilities of these woods for reproduction, and if the naval store industry is continued in the same profligate way, and the devastation by fire and domestic animals is not arrested, their extermination for all practical purposes is certain. During the earliest part of its development the Long-leaved Pine grows slowly, so that the young trees are easily suppressed by competing species even under the best conditions. Again, it is impatient of shade and needs direct sunlight both for germina-

tion and for growth. Besides this there are only occasional seasons when it seeds abundantly, and if the seed falls in a wet, undrained soil its sprouting power is lost. Left to the ordinary course of nature, then, the Long-leaved Pine would have a small chance of successful reproduction, but when to its ordinary enemies the influence of man is added, we can easily see why its offspring rarely takes the place of the parent tree, even in regions most favorable to its natural renewal. The economic conditions of the present are hardly such as to justify an attempt at artificial reforestation, but the importance of this valuable timber to the industrial and commercial prosperity of the people of the country which it inhabits ought at least to suggest to the owners that its natural reproduction should be encouraged.

The Cuban Pine, *Pinus heterophylla*, has a greater capacity for natural reproduction than the Long-leaved Pine, and it is easier to renew in forest artificially. It grows with greater rapidity; it furnishes timber of large dimensions as good as that of *P. palustris*, and it yields resin in abundance. On this account, Dr. Mohr concludes that for reforesting the low Pine lands of the southern-coast region, where it is already making an aggressive growth, it is to be preferred not only to any tree within its original habitat, but that it will be useful far beyond the range of its natural distribution. Very interesting, too, is Dr. Mohr's account of the Short-leaved Pine, *Pinus echinata*, which stands next to *P. palustris* in the importance of its timber. The wood takes as good a finish, and is more easily worked, being softer and containing less resinous matter than the timber of the Short-leaved Pine, and it is therefore often preferred by the cabinet-maker and house carpenter. Fortunately, too, the tree produces abundant crops of seed almost every year, and it makes a successful struggle with competing trees in the shade or sun, so that it soon takes possession of the soil with a little assistance from the hands of the forester. It is also of great advantage to the farmer because it furnishes him with an easy method of restoring a tree covering to denuded uplands.

The Loblolly Pine, *Pinus taeda*, is a tree of more economical importance than was once supposed. It is as aggressive a grower on the coast plain as the Short-leaved Pine is on the rolling uplands of the interior. The rapidity with which it colonizes clearings and old fields has given it the common name of Old Field Pine, and the tenacity with which it retains the ground which it has once possessed for its own seedlings, points to its value in forest management. It also produces abundant seeds, it grows rapidly, and although the timber is in some respects inferior to that of the Long-leaved and Cuban Pines, it will probably play quite as important a part in the forestry of the future as will the Short-leaved Pine.

The Spruce Pine, *Pinus glabra*, is the only really soft Pine of the southern states. It is the least common of the Pines of this region, never forms extensive forests, and for the most part is scattered among broad-leaved trees, both deciduous and evergreen. It has, however, the great advantage of thriving under shade, and for which purpose it will, no doubt, be largely used by the trained foresters of this region in generations to come.

The wood of all these trees is similar, not only in appearance, but in minute structure, and the characteristics and anatomy of each, as concisely recorded by Dr. Roth, who has charge of the timber physics of the department, make an extremely interesting paper. The discussion of such points as the differences between sap and heart-wood, and between spring and summer wood, and the like, are illustrated by plates of cross-sections, magnified views of resin ducts and other histological details, so that even the general reader can find much to claim his attention. Mr. Fernow contributes an introduction to the whole, in which he sums up the work of Dr. Mohr and Mr. Roth. He offers diagrams to show the comparative growth of average specimens of the different species during a given time, in height, in diameter and in volume, and, altogether, he makes a clear summary of

the work for the general reader. Judging from the best data at hand, Mr. Fernow concludes that the pine timber standing and ready for manufacture may reach two hundred thousand million feet, while the lowest annual consumption of the future will probably be seven thousand million feet. He does not, therefore, prophesy that the pine supply of the south will be exhausted in forty or fifty years, for if we should begin rational forestry now, the forests may be kept as a source of natural supplies even though these supplies are reduced. But, after a review of the recuperative powers of the various species, he says: "Considering that the timber on which we now rely and on which we base our standards came from trees usually from 150 to 200 years or more old, and that none of these Pines make respectable timber in less than from sixty to 125 years, the necessity of timely attention to their renewal is certainly apparent." To this moderate statement every thoughtful person will give unqualified assent.

### Notes.

The bushy tops of branches of young Long-leaf Pine-trees were among the handsomest offerings for decorations during the holiday season. Gray Spanish moss and large Palmetto-leaves, also from Florida, were more freely used than ever before, and the supply of English and southern mistletoe was all sold before Christmas Day.

Mr. I. H. Cammack, in a recent address before the Southern California Fruit-growers' Institute, says that the Anona Chermolia, the tree which produces the chermoyer, is now growing in several places in California, and it probably will thrive in any climate not too severe for the Lime. The fruit matures in the winter and spring, and it can be gathered while firm and shipped for several days' journey successfully. The color of the fruit is brownish yellow with a reddish cheek. It is somewhat heart-shaped, contains few seeds, and it is very rich and is considered by many as a most delicious fruit, although it is not relished by all persons when they first taste it. The trees come nearly true from seed and begin to bear about the fourth year.

The Roselle, Hibiscus Sabdariffa, is a native of tropical Asia, resembling the Okra in growth, possessing great resistance to drought and yielding an acceptable food-product. It has been tried in agricultural stations of southern California, where it is said to be ornamental, with dark red stems and pods showing through rather scanty green foliage. The juice from the fleshy calyces makes a cooling acidulous drink and is useful for jelly. The mucilaginous properties of the juice render the setting of the jelly certain, and its dark cherry color and sprightly acid make it very desirable. As it will grow in hot, arid situations, Mr. Wickson, of the Experiment Station at Berkeley, is distributing seed to those parts of the state where it will thrive.

Winterberries may now be seen in the wholesale markets by the crate, and cost fifteen cents a quart. Large bright red Tangerines, from Florida, cost sixty-five cents a dozen, and the smaller and paler Mandarins, from Italy, sell for the same price. Grape-fruit, which is becoming scarce, costs twenty-five cents for large fruits of even color, from Florida. Coe's late red plums are still seen in some of the high-grade fruit-stores, and luscious, fully ripened persimmons, from Florida, the latter costing \$1.50 a dozen. Small round baskets holding fifteen beautifully grown strawberries, picked with long stems, sell for \$2.25 to \$3.00. Hot-house melons, Spanish melons and prickly pears may be had at fancy prices. The last of the Comice pears were sold during the holiday season, and the russet Winter Nelis, the deep green Easter Beurre, the bright Forelle and spicy Seckel pears are now among the best. Small Strawberry pineapples, from Florida, cost fifteen cents each, and large Abaco pineapples, grown under shelter, from Orlando, in the same state, cost \$1.00. Mushrooms, cucumbers, tomatoes as even and showy as any choice fruit, and asparagus, are offered in the best fruit-stores. The latter vegetable is tied in bunches containing a dozen stalks a foot in length, and costs \$1.00 for this quantity.

The possibility of growing Cauliflower under glass with profit was last year tried in the Missouri Botanical Garden, and at the meeting of the Society for the Promotion of Agricultural Science, held in Buffalo last summer, Mr. H. C. Irish gave an interesting account of the methods of cultivating the

crop. An interesting part of the experiment was the successful growing of Lettuce between the rows of Cauliflower. Lettuce will not mature good crops among the Cauliflower-plants unless they are set eighteen inches apart, but since a given area will produce nearly as much Cauliflower in weight when the plants are set at this distance as it will when the plants are set more closely, it is possible to get crops of both vegetables, and the lettuce will be clear profit beyond the income of the Cauliflower. Later on, Cucumber-vines were set around the sides of some of the benches between the Cauliflower, with a view to training them up the roof, and others to run over the benches when the Cauliflower were removed. A row of Chervil was also planted around the sides of the benches, from which many leaves were cut for garnishing, and it proved to be a good plant for that purpose. Mr. Irish estimates that since one man could attend to a house 170 feet long by twenty-four feet wide, with two walks and 100 square feet of bench-room, that the cauliflower, lettuce and cucumbers would bring in the winter a total income which might amount to \$1,150, which, after deducting expenses, would be something over \$860 for interest on the investment and the labor of one man.

Bulbous plants are now represented in the florists' windows by flowers of Freesia, Daffodils, Chinese Narcissus, Roman Hyacinth, Lily-of-the-valley, Lilium Harrisi and L. longiflorum. The yellow and white French daisies, white lilac, forget-me-nots, sweet peas, camellia, daphne odorata and showy bracts of poinsettia are noticeable. In collections of standard varieties of roses Ulrich Brunner and Magna Charta are occasionally seen, and the comparatively new President Carnot. Many lots of Orchids and other costly flowers were frozen in transit to the wholesale dealers during Christmas week, and the prices and sales of cut flowers were greatly affected by the cold weather. Much of the stock had been held back for the holiday trade, and the proportion of low-grade flowers was thus unusually large. As the dealers handle only the best stock and the Greek street venders could not carry on their trade, sales were limited to the best grades, and immense quantities of poorer flowers remained unsold and went to waste in the wholesale establishments. Red carnations were in marked favor, and Meteor, Portia and Garfield sold readily at fair prices, as did good yellow carnations, while there was almost no demand for white ones, and pink varieties sold slowly, except those of the highest quality. On Christmas and the day preceding about 1,700 bunches of violets, each containing a hundred blooms, were bought by retail dealers. American Beauty roses were most in demand in their class, and selected flowers sold at retail for \$2.50 apiece. The Christmas trade in cut flowers was, altogether, satisfactory to the retail dealers. Growing plants in fancy baskets were more popular than ever before. New Year's day failed to stimulate the flower trade, and the day was scarcely more busy than an ordinary Saturday during the winter season.

According to the London *Times*, the forests of western Australia are exceedingly rich in trees of economic importance, among which the Jarrah, or Eucalyptus marginata, is now the most important. In constructive work, where wood is brought into contact with soil and water, this timber is superior to that of any other wood in that forest. A healthy tree of average size is from ninety to a hundred feet high and from two and a half to three and a half feet in diameter at the base, and it will grow so as to produce logs two feet through at the base in about fifty years. It grows in sections where the rainfall ranges from thirty-five to forty inches in the year, and the wood when dried weighs sixty pounds a cubic foot. It is red in color, takes a good polish, is easily worked, and is good for piles, bridges, boats, furniture, railway-sleepers and charcoal. It is usually found mixed with or near the Karri, or Eucalyptus diversicolor, a giant species, straight and regular in growth, umbrageous in appearance, good specimens being two hundred feet high, four feet in diameter breast-high, and with a stretch of 120 to 150 feet from the ground to the first branch. It is a rapid grower and will produce marketable timber in from thirty to forty years. This wood is red in color, very much resembling that of the Jarrah. Its texture is hard and heavy, and it is tough and not easily dressed. For bridge planking, flooring and beams it is unequaled by any wood in the colony. Karri timber is largely exported to London for paving the streets since its surface is not easily rendered slippery. There are other valuable trees in this forest, the timber in which is estimated to be worth more than six hundred million dollars. Two thousand men are now employed in cutting timber, and the output last year represented a gross value of two million dollars, and this will be increased by the end of the century to at least ten million dollars.

Park-making as a National Art.

THE *Atlantic Monthly* for January contains a noteworthy article under this title by Mrs. M. C. Robbins, who is well known to the readers of this journal. Her thesis is that the desire for the creation of beauty in America will find its fullest expression in the design and construction of public parks rather than in painting, sculpture or architecture. We have already done well in these latter fields, but our craving for liberty, and for enlarged and untrammelled utterance, can only be satisfied by bringing under control the mighty forces of nature and compelling them to develop and make manifest our artistic ideas. It is a significant fact that America has already produced one preëminent artist in this field, and that the park systems of several American cities are unrivaled for grandeur of conception.

The article presents a specific phase of a more general subject discussed by Mrs. Robbins in the December number of the same magazine under the title of "The Art of Public Improvement," a phrase meant to include in a large and rather vague way every effort of individuals and communities to preserve and transmit to posterity what is most beautiful and interesting in nature. This tendency is manifested in the reservation of tracts of forest land, the increasing number of parks and playgrounds, the improved care of towns and villages, the rescue of beautiful landscapes from defacement and the preservation of objects of historical interest. This inclination is in accordance with the genius of the English race, and especially with the fresh young branch of it which has found itself with a continent to work upon. In our youthful exuberance we long for something that will appeal to all the people—something colossal and distinctly American—and this so-called Art of Public Improvement will find full scope in treating vast areas of mountain and cataract and forest in works of sufficient moment to need the support of sovereign states, or even of the Federal Government, and which need an army to protect them. This art must be democratic to suit the American character, large and simple, so that it may be intelligible, not only to a cultivated class, but to the average mind. We have room enough to give free hand to our desires, for with little cost we can secure public reservations of enormous extent, yet of remarkable

natural beauty, for we still possess square leagues of primeval forest which are incomparably more impressive than the planted trees of European woodlands. That a sentiment like this is growing and seeking to find expression in every direction is seen in the establishment of the great forest reservations in the west; in the rescue of such places as Niagara, Yosemite and Yellowstone for public use; in the preservation of the battle-fields of the civil war as "mementoes of the most tragic period in our country"; in the foundation of societies for preserving in more than one state beautiful and historical places; in the purchase of spacious game preserves by clubs; in the establishment of the Arnold Arboretum and many botanic gardens; in the greater simplicity shown in the ornamentation of rural cemeteries; in Arbor Day; in village improvement societies; in improved roads and school-grounds. Mrs. Robbins' conclusion is that "there is everything in the United States to nourish a great art—wealth, enthusiasm, generosity, a sense of boundless capacity, the verve and spring of youth and unlimited aspiration. In the Art of Public Improvement, the dreamer and the utilitarian can combine, the nation's beauty and the nation's wealth can in it be united, and our achievements may be such as to satisfy even American ambition."

In the article devoted more specifically to park-making, it is pointed out that the ancient pleasure-grounds of the Old World originally belonged to sovereigns and were paid for by taxes wrung from the people who could not enjoy them. In this country, however, all parks of any extent have been designed for the people, and although they have been created within a single generation they are a constant source of delight to all, and they rank in extent and beauty with any resorts of the kind in the world. The rapidity with which the acquisition of park lands by cities has been going on will be understood when it is remembered that in 1869 there were only two well-advanced rural parks in the United States. Fifteen years later there were twenty, and now there is hardly a city of consequence in the country which has not made the beginning of a system of parks and parkways. It is true, as Mrs. Robbins says, that when the schemes now begun have been fully carried out we shall have public reservations reaching, in what is practically an unbroken series, from the eastern seaboard to the shores of California. "The idea of such a continuous reservation, a national parkway from the Atlantic to the Pacific, leading from one beautiful pleasure-ground to another, or passing through great tracts of woodland controlled by Government foresters, is not inconsistent with the genius of our country, which ever seeks a closer union between its parts; while the gradually enlarging park systems of our cities indicate the way it may be brought out in the linking together of suburb to suburb by great boulevards, which tend to bring civilization to distant homes by affording safe and easy communication between them."

Our people have not always been wise in selecting their grounds, but they have usually developed them in an artistic way and have held the necessary constructions in true subordination to the natural character of the scenery, and in this way they have been an educating influence in the growth of popular taste. An attractive park stimulates the desire for appropriate home surroundings, and a visitor to these well-kept pleasure-grounds carries away lessons which are put to practical use at home. In this way the park becomes the common school where the first lessons are taken in the distinctive art of the nation. Hundreds of thousands of people, for example, who saw at the Columbian Exposition how quickly miles of newly made shore could be fringed with beautiful vegetation went away with memories of that fairy-like scene which will never be effaced, and with new ideas of what can be accomplished by refined and restrained art in waterside planting. Every example of the kind tends to chasten and purify taste, and to furnish ideals which will be realized in years to come in private and public grounds all over the country.

It must not be supposed that there was no opposition to this movement in favor of public parks when it first began. Indeed, the vigor of the movement can only be estimated by the opposition it created at the outset. When, after long argument, the land for Central Park was acquired, good people feared that it would simply be a field for the development of riot and license among its frequenters, and even after the enterprise was well advanced a leading newspaper in this city pronounced it "all folly to expect our country to have parks like old aristocratic countries." It was argued that reputable gentlemen and ladies would never consent to associate themselves with rowdies and nursemaids, and eminent citizens declared that no gentleman would ever resort to it or allow his wife and daughter to visit it. Lawyers affirmed that it would be impossible to police so large a space, and one wealthy gentleman protested against the extravagance of its construction, and asserted that the designs were quite fine enough for his own private grounds. Fortunately, the Park Commissioners were men of nerve and intelligence, and they were clothed with extraordinary powers, so that they rushed the work, employing thousands of laborers at once to get it beyond the reach of those who were bent on stopping it. It need not be added that it required only a few years' experience to demonstrate that the influence of the park was refining instead of degrading, and that the fourteen million dollars which it originally cost was one of the most fruitful investments the city ever made.

We no longer hear objections of this sort against park-building, but there is another danger that ought to be shunned. It is not enough to secure a certain number of acres wherever they can be had with least cost and trouble. In the first place, the land should be wisely selected and its boundaries intelligently determined. Design for its improvement must be made by competent artists and executed with skill. When completed, pleasure-grounds must be maintained with care, for, if left to uncontrolled nature and unpoliced, they may become repulsive desolations. To secure a good design we need a school of landscape art, for, although such a school will never create a great artist, it can teach him the history of what has been done, point out to him what tools he needs and how to use them, and show him how he can most directly reach his end. Graduates of such a school, with added instruction in horticulture and engineering, ought not to commit any gross offenses against good taste in Landscape Art.

Mrs. Robbins' article includes an interesting sketch of the park enterprises in many of our great cities, and although all readers will not be convinced by its optimistic tone that the millennium of pure art is at hand in America, it will be found instructive and stimulating.

#### Classification of Varieties of Peaches.

THAT there are well-defined types of Peaches which behave differently in different latitudes is well known, and some knowledge of the classification of varieties as affected by climate is necessary, not only to the practical grower, but to the scientist as well. The Peach has been so modified by climatic influence and crossing of the different types that it is difficult to devise a system which will include all varieties and not be subject to some criticism. But if a system can be devised by which one can distinguish a large number of varieties and predict within a reasonable degree of certainty which types are likely to succeed in a given section, a long step is made in the direction of most valuable knowledge. The one based upon the presence or absence of glands on the foliage is of considerable value in distinguishing varieties in the nursery before they fruit. But we have varieties which bear different glands upon the same tree. Seedlings from a given variety may bear entirely different ones, and vary also in the adherence or non-adherence of flesh to the pit. And this is true even when the variety has been fertilized by its own pollen.

There are types coming from China, Japan and Java, and others which are now being built up in the southern part of the United States, which the above points do not distinguish with clearness. We have seedlings from the Honey Peach which

came from China in 1854; seedlings from the Peen-to, which came from Australia in 1863; then, again, there are seedlings of the Spanish or Indian type; all of which are adapted to more southern latitudes than those of the Persian strain, which constitute the bulk of northern orchards. These new types are proving valuable along the Gulf states, where the Peach has not been grown as successfully as it has farther north. It is important now that the botanical characteristics of each type (which we shall call race for a better term) should be recorded with clearness, and the climate in which each grows best be pointed out.

During the past four years the Peach has been one of my special studies. Our experimental orchard contains 190 varieties. Large experimental orchards have been studied near the Gulf and over a thousand miles farther north. From what I have thus learned it seems to me that what is known as the "Onderdonk classification" is the best. An outline of this scheme appears in the report of the United States Department of Agriculture for 1887, page 648. Some of the distinctions made in this classification cannot be noticed with decisive clearness a few hundred miles farther north, but in the semi-tropical climate of the coast region the characters are striking. This at once indicates that the different races originated in different degrees of latitude and at different altitudes. These facts are further substantiated by botanical characteristics. We divide the Peaches now cultivated in the United States into five races: (1) Peen-to, (2) South China, (3) Spanish or Indian, (4) North China, and (5) Persian. By race is meant "a variety so fixed as to reproduce itself with considerable certainty by seed."

SEED CHARACTERISTICS.—The shape, size and corrugations of the seed are so well marked in the more distinct representatives of the different races that after a little practice one can distinguish them apart by this means alone. This can be readily seen from the figure (see page 13) from a photograph.

It will be seen that the seed of the Peen-to is nearly round, much compressed at the ends, corrugations small and somewhat rounded. The seed of the Honey is oval, with apex slightly recurved, corrugations slight, prominent flange on one side. Seed of Spanish is large, oval, nearly flat, apex prominent, corrugations very long and wide, at the base they run more longitudinally than in any other race, flange on one side often prominent. Seed of North China is nearly round, very thick, corrugations rather slight and irregular, apex rather prominent. Seed of the Persian is somewhat round, more flattened at the base than any other, corrugations prominent toward apex, but very seldom extend to base, apex more or less prominent. A resemblance can be seen between the Spanish and Persian, and as there is no definite history in regard to the origin of the Spanish it is probable the types had the same origin. The Indian type of the Spanish can only be distinguished from the Persian in many cases by the heavy down on the fruit, which is characteristic of the Spanish.

#### THE DIFFERENT RACES AS AFFECTED BY CLIMATE.

I. PEEN-TO (*Prunus platycarpa*. Decne.) Tree rather large; branches vigorous, willow-like, branching at an angle of about forty degrees; flowers large, opening early, frequently in January in the Gulf states, often at a low temperature and very irregularly; leaves narrow and long, inclined to be evergreen; fruit much flattened; skin white and mottled with carmine; flesh white; flavor sweet, with peculiar almond tang. It is adapted to the northern part of the Citrus belt, in which climate it ripens from May 1st to June 1st. It has a tendency to sport, and some valuable varieties are now coming from it for the extreme southern part of the Gulf states where other races will not grow successfully.

II. SOUTH CHINA RACE.—(The parent of this race is the Honey Peach, *Prunus Persica*. B. & H.) Tree medium-sized; branches leaving the trunk at an angle of about fifty degrees and curving upward; buds quite prominent; flowers always large and very abundant, with greater resisting power against cold than any other race tested in this climate; has borne crops annually during the past four years, when many other varieties belonging to different races failed; foliage small, slightly conduplicate, distributed all along the limb, color dark green, in fall slightly tinged with red; requires short season of rest; fruit rather small, somewhat oval in shape, slightly flattened, suture very deep at basin, but does not extend more than one-third the way down; apex long and recurved; flavor peculiar, honey sweet. Supposed to have originated in southern China, from which the seed came. This race is adapted to more southern climates than any other, except the Peen-to. Honey seedlings are proving very valuable for the southern Gulf states.

III. SPANISH RACE.—Tree very large, except in Indian type,

which evidently has considerable Persian blood, judging from the color of the young wood, which is reddish, the naked places on the bearing wood and the corrugations on the pit and its general shape; limbs large, long and spreading; branches low and drooping; flowers nearly always large; leaves small and flat, persisting late in fall and turning slightly yellow; fruit very decided in character, ripening very late, nearly always yellowish when mature, and covered with heavy down; in the Indian type the fruit is striped with red; a heavy bearer and sure cropper in its proper isotherm. Seems to have come from the Indian type brought over from Spain by the Spanish missionaries and distributed among the Indians of the extreme southern states. Perhaps it is owing to successive seedlings in more favorable climate that the type is now varying. All over the southern states one hears the expression that seedlings are surer bearers than budded trees, and there seems to be some truth in this belief, because by growing seedlings continuously varieties may adapt themselves to climate. This type is adapted to isothermal lines north of where the South China race flourishes.

IV. NORTH CHINA RACE.—The original Chinese Cling, which is a dwarf tree near the coast, is the parent of this race. It is not at all adapted to regions along the Gulf. Two or three hundred miles farther north it and its seedlings do well. It is the parent of the largest peaches in the United States; blooms later than the Persian, and the flowers are nearly always large; foliage large and flat, turning toward autumn in the southern states to a peculiar pea-green, and this type among others in an orchard can be detected with ease by this means alone. The color of the foliage foreshows the color of fruit, as none of the seedlings, as a rule, are highly colored. The parent came from China, and it is adapted to zones farther north than those suited to the Spanish.

Fig. 3.—Peach Pits.—See page 12.

1. Peen-to.      2. South Chinese (Honey).      3. Spanish or Indian (six varieties).  
4. North China (Chinese Cling variety).      5. Persian (Old Mixon Free variety).

V. PERSIAN RACE.—Tree medium size to large; limbs short and thick, with long naked places; bark usually rich purplish red on young wood; flowers large or small in different varieties; foliage crimped and conduplicate, with purplish tinge before falling, which happens early. This race requires a long period of rest, which indicates that it has had a more northern origin than any other, supposed to have been Persian. The seedlings now form the bulk of northern Peach orchards. Fruit usually the most highly colored and of the finest flavor. In this race we sometimes find a variety with yellow flesh, but the flavor is not as good as the others. It is almost useless to plant this race in the southern part of the Gulf states.

There are some ornamental varieties which will not be mentioned here.

Experiment Station, College Station, Tex.

R. H. Price.

It is a mistake to suppose that the value of charming natural scenery lies wholly in the inducement which the enjoyment of it presents to a change of mental occupation, exercise and air-taking. Besides and above this, it acts in a strictly remedial way to enable men to resist the harmful influences of ordinary town life and recover what they lose from them; in short, to establish sound minds in sound bodies. It is thus a sanative and restoring agent of vital importance to the health and strength and to the earning and taxpaying capacity of a large city, and to the mass of the people it is practically available only through such means as are provided by rural parks.

Frederick Law Olmsted.

### London Letter.

LECTURES ON HORTICULTURE.—The Royal Horticultural Society continues to provide lectures for its bimonthly meetings at the Drill Hall, and the bulk of them are a success. Next year's programme contains some items of more than usual interest, namely: "Microscopic Gardening," by Professor Marshall Ward, of Cambridge; "Artificial Manures," by Mr. J. J. Willis; "Diseases of Orchids," by Mr. G. Massee, F.L.S., of Kew; "Physiology of Plants," by Professor S. H. Vines, of Cambridge; "Mutual Accommodation between Plant Organs," by Professor G. Henslow; "Roots," by Professor F. W. Oliver, and "Sporting in Chrysanthemums," by Professor Henslow. In addition to these scientific lectures by eminent specialists, there will also be lectures upon practical subjects by leading practitioners. These lectures are all afterward published in the society's journal. The great exhibition at the Temple is announced for May 26th, 27th, 28th, and the exhibition of fruit at the Crystal Palace for September 30th and October 1st and 2d. These exhibitions have become an important annual institution in London.

HORTICULTURAL EXHIBITION HALL.—Since the Royal Horticultural Society left South Kensington, horticulture has been without a suitable exhibition hall in a central position in London. An attempt was made two or three years ago to raise a sufficient sum to build a hall and offices for the society, but from some cause or other this proved abortive.

It is now proposed that, in commemoration of the Queen's long reign, next year a Victoria Palace or Queen's Hall for Horticulture should be built in London, Mr. J. L. Wood, a professional horticulturist, having drawn up an elaborate scheme, the plans of which are published in the gardening papers, and which might, perhaps, provide all that is needed. This scheme is, however, a very costly one, and it is questionable if the money would be forthcoming for it. There is no better plan before the public than the proposed amalgamation of the Royal Horticultural and the Royal Botanic societies. For this little or no money would be required, and the needs of metropolitan horticulture would be fully satisfied.

RAILWAY RATES FOR GARDEN PRODUCTS.—English growers hitherto have had good cause for complaint against the excessive charges made by the railway companies for the conveyance of their products, compared with the charges made by the same companies for the conveyance of foreign products from port to market. The Great Western Railway has set a good example by making considerable reductions in their rates for agricultural, garden and dairy products carried by their passenger and goods trains. They are also willing to collect small quantities, under certain conditions, and to charge for them in the aggregate as if they were one consignment of from ten hundredweight, the minimum, up to three tons, the maximum. Thus small growers in the same neighborhood may, with little trouble, combine for the purpose of marketing their products on favorable terms. Hitherto the cost of sending a few bushels of apples a hundred miles often exceeded what they would fetch in the market. At the present time I have to pay six shillings for a bushel of poor apples, fit only for cooking, and I am told that there are plenty of growers in the country who would be glad to get two-thirds of that price for good home-grown fruit.

PUBLIC GARDENS AND OPEN SPACES.—A joint committee formed by the Commons Preservation Society, the Kyrle Society, the Metropolitan Public Gardens Society and the National Trust for places of historic interest, with a view to commemorating the Queen's long reign, has drawn up a scheme by which it is proposed that every locality should dedicate a plot of ground to the use and enjoyment of the people, and to be called a "Queen Victoria" garden, park,

playground, or whatever name would be appropriate. "We aim," says the committee, "at connecting the memory of the Queen with something which will permanently make a neighborhood more healthy, more agreeable, or more interesting to live in. The exact form which such a memorial would take might vary largely in different places. In the metropolis and other towns there may be square gardens or disused burial-grounds, or other lands, which have been hitherto, by some accident, saved from the builder, but which are doomed either to absorption into the surrounding areas of bricks and mortar, or to waste and neglect; to recover such spots, and place them under the management of the town authority, would be an invaluable memorial of the Sovereign's long and beneficial rule. Finally, there may be some earthwork or ruin of great interest, or even some building of rare architectural beauty or historic associations, which might be purchased and devoted to some public purpose, and which would form a possession of unique value for future generations."

**THE FLORA OF BRITISH INDIA.**—The first part of this monumental work was published in 1872; the twenty-second and last part was issued a few weeks ago. It is, perhaps, the largest, most complex and the most valuable of all the large Floras prepared at Kew, and it is mainly the work of Sir Joseph Dalton Hooker, who, be it remembered, is now in his eightieth year. As a very large proportion of popular garden plants, particularly Orchids, are included in this Flora, it has a special interest for horticulturists. The descriptions, which are in English, are clear and concise, so that one has little difficulty in identifying plants by their means; the synonymy, references to figures, etc., are exhaustive (one might say of synonyms that they are often exhausting in their number). The whole work is in seven volumes. It is not a work for the ordinary library, but as a book of reference it has great value for the botanical cultivator and writer. Such plants as Rhododendrons, Ferns, Orchids, Palms, Bamboos, Liliaceae, Aroids, Begonias, Ixoras, Hoyas, Primulas, Gentians, Acanthaceae, Ficus, Quercus and Scitamineae (Hedychium, Musa, etc.), are very largely represented in the regions comprised within the area termed British India. That vast and varied stretch of country known as the Himalaya has yielded more good garden plants, perhaps, than any other similar region in the world, not even excepting South Africa, for while the Ericas, Proteas and many bulbous plants which used to be grown in English gardens are now never seen, except in horticultural picture-books, the Himalayan Rhododendrons, Dendrobiums, Primulas and hosts of other things are growing in popularity. The Orchid grower alone owes a large proportion of the most beautiful and useful of his favorites to British India.

**THE SUGAR QUESTION.**—The sugar-growing industry in the West Indies is threatened with ruin from the crushing competition of beet-sugar. The British Government has, therefore, appointed a Commission to inquire into the condition and prospects of the islands affected, with a view to helping the planters and others concerned. The Commissioners are Sir Henry W. Norman, Sir Edward Grey and Sir David Barbour, and Dr. Daniel Morris, Assistant Director at Kew, has been appointed to accompany the Commission as expert adviser in agricultural and botanical questions. Dr. Morris's experience in Ceylon, the West Indies and Kew specially qualifies him for work of this kind. Kew initiated a policy for the development of the economic resources of the West Indies more than twenty years ago, and the fact that Jamaica entered with spirit into this movement, no doubt, accounts for the better condition of things in that island compared with others.

**MESSRS. J. VEITCH & SONS.**—The famous nursery and seed business known all over the world as "Veitch's" is following the example of many other large commercial houses and will shortly be floated as a limited liability company. Mr. Harry Veitch will act as Director-Chairman, and his nephew, Mr. James H. Veitch, will be managing director.

Mr. R. WARNER died on December 17th last in his eighty-third year. He has held a prominent place among the leading amateur Orchid growers for about fifty years. The late Mr. B. S. Williams, the Holloway nurseryman, was once upon a time Mr. Warner's gardener. The *Orchid Album* was the joint production of Messrs. R. Warner and B. S. Williams, and I believe Mr. Warner assisted in the production of *Williams' Orchid Grower's Manual*. His *Select Orchidaceous Plants* is held in high esteem. His garden at Chelmsford was famous for the large, well-grown specimens of Orchids, especially Cattleyas, produced in it. He was also a keen grower of hardy fruits. English horticulture can ill afford to lose such men.

## New or Little-known Plants.

### *Aster tardiflorus*, L.

IN a recent paper\* I have discussed the history of this species, showing how, through lack of familiarity with the plant and through a desire to find something American to which we could attach its name, many forms of common New England species have been passing as *Aster tardiflorus*. On the other hand, most of the American material of true *A. tardiflorus* has been called *A. patulus*, Lam. That the two species are identical there can be no doubt. They were both described from specimens introduced into European gardens from north-eastern America, and as *A. tardiflorus* was published by Linnæus twenty years before Lamarck described *A. patulus*, the Linnæan name should be reserved for the plant.

*Aster tardiflorus* is not generally a common plant. It is found in its greatest development, perhaps, in the valleys of the White Mountains, whence the Messrs. Faxon annually bring many puzzling, but interesting, forms. The plant is generally, though locally, distributed through Maine and western New Brunswick, and it has been collected at a number of points in Vermont. Two extreme stations occur in Massachusetts, but west of New England the occurrence of the species is not yet clearly known.

Like most of our other New England *Asters*, *A. tardiflorus* shows a strong tendency to intergrade with a large number of species. The specimens examined both in the herbarium and in the field pass by various degrees of modification to *A. Novi-Belgii*, *A. longifolius*, *A. puniceus*, *A. Lindleyanus* and *A. prenanthoides*, yet the typical plant will hardly be confused with any of these. Mr. Faxon's drawing (see p. 15) shows the typical form of the plant. In fact, it may be taken as the best available representative of the species, for the drawing is made from specimens which were cultivated at Kew in 1881 as *A. patulus*, and which, after comparison in the Linnæan herbarium, Dr. Gray marked, "This would answer quite to the flowering specimen in herb. Linn. of *A. tardiflorus*."

The species is not always so smooth as represented in the drawing, but it passes gradually from the glabrous plant to a form in central Maine and the White Mountains, with the stems and the midribs beneath densely white-villous. A form in Maine and eastern Massachusetts having elongated and narrow leaves with stout and scattered salient teeth and a very contracted inflorescence is the var. *lanceifolius*, Fernald. Another striking form which has been described at some length in the article previously cited is what may be a hybrid between *Aster puniceus* and *A. tardiflorus*, var. *lanceifolius*. The plant is striking and unique, with its puniceous like stem, short, dense inflorescence of showy heads, and leaves intermediate in outline between the two supposed parents. This plant has been found in some abundance at several places in eastern Massachusetts the past autumn, and further study is necessary before its true affinity can be determined.

### Tender Sub-aquatic Plants.

**E**ICHORNEA CRASSIPES and *E. azurea* succeed well in soil which is continually soaked with water, and if the soil be enriched with cow manure the display of bloom after midsummer is much superior to that on floating plants. Self-sown seeds of these two species germinate out-of-doors here after lying in the ground all winter, and the seedlings in their turn ripen seed, so that in places where the surroundings are favorable they may become naturalized. Another plant which does best where there is a continual supply of moisture is the Parrot's Feather, *Myriophyllum proserpinacoides*. It has rather inconspicuous flowers; the foliage, however, is of such a pleasing shade that it is always welcome. When grown in water, the foliage under the surface is much finer or thread-like than that above. Last summer I saw some plants of it grown in tubs of moss mixed with manure, the bottoms of the tubs just resting in the water of a lily pond; it was during the middle of June, and even at that early date the sides of the tubs were entirely covered with the long feathery growths. Although a native of Brazil it is perfectly hardy here.

We have several desirable species of *Cyperus*, and among the dwarf kinds we find *C. alternifolius* and its variegated form the best for margins of lakes, where, if planted early, they make a fair show before the summer is far advanced. The variegated form is slower in growing than the other. *C. Papyrus*, known also as *Papyrus Antiquorum*, although often successfully used as an aquatic, will do well where the soil is fairly moist. In positions of this kind the stems are stouter and better able to withstand high winds. Both of these are tender and require greenhouse protection during winter. *C. Papyrus* often ripens seeds, and these, if sown as soon as ripe in finely chopped sphagnum moss, kept moist and placed in heat, germinate freely.

*Gunnera scabra* and *G. manicata* are desirable for their foliage on the margins of ponds. They will not endure much frost, however, and are a trifle difficult to raise from seed. A plant much easier of cultivation, with almost as handsome foliage, is the Chinese Rice Paper Tree, *Aralia papyrifera* (*Fatsia*), which will grow ten feet high from strong roots or crowns in a single season. It is not reliably hardy north of Washington. In most places ashes or rough litter over the crowns will preserve it. It is propagated from cuttings of the root about the thickness of one's finger and two or three inches long. If these are put in pots in a cool propagating-house, they will make full-sized plants the following season. Two species of *Thalia*, *T. divaricata* and *T. dealbata*, do admirably where they can have a little extra attention in the shape of good soil. *P. divaricata* is the larger of the two, having leaf-blades nearly a foot long and six inches broad on stalks two to three feet long. The small purple flowers are borne on scapes from three to five feet high. The foliage of both resembles that of some species of *Canna*, to which genus they are closely related. *Stromanthe sanguinea*, belonging to the same family, has proved fairly satisfactory, the past two seasons, in situations partly shaded from the sun. Two of the best-known *Colocasias*, *C. esculenta* and *C. odorata*, give quick results where broad tropical foliage is needed. *C. esculenta* is stemless, with the leaves pointing to the ground. *C. odorata* has the foliage more upright and is the more rapid-growing of the two. It has thick succulent stems, sometimes six feet long. Where color is wanted the fancy-leaved *Caladiums* are quite at home where they have rich damp soil to grow in. Those kinds lately introduced with very highly colored leaves should be avoided, as they do not succeed nearly as well as some of the older sorts, such as *Bicolor*, *Dr. Lindley*, *Rossini*, *Duchartre Cannartii*, *Beethoven*, *Uranus* and *Pictum*. The bulbs should be started indoors and put in their summer quarters late in May or early in June, as when put out earlier, they are apt to get a check from which they need some time to recover.

Botanic Garden, Washington, D. C.

G. W. Oliver.

### Seasonable Work.

**S**ILENE pendula is among the showiest of early-blooming plants useful for spring bedding. It is a biennial, and naturally would sow itself one season and bloom the next. Under cultivation our summer-sown seedlings have invariably died during the succeeding winter, although protected, while, curious to note, such as were self-sown stood unprotected. We do just as well by making a sowing indoors, during late January or February. The seed germinates in about three weeks, and the seedlings are transplanted as soon as large enough to

handle. Unless well aired they damp off easily, and we place the flats on shelves near the glass. They remain here until the end of March, when we shift them into cold frames to harden, a few weeks before planting time. The plants commence blooming early in May and remain in full beauty for the whole of the month. One merit of *S. pendula* as a bedding plant is that it never looks untidy.

*Vinca rosea* and its white variety make an attractive mixture for summer bedding. It is slow work to get a stock of it, for it germinates slowly, and even then almost stands still, and not until we can give it a little bottom-heat does it make any growth to speak of. It is one of the most beautiful plants for a summer display, and helps greatly to vary the too frequent repetition of *Coleus* and *Geranium*.

Spring is already approaching, and what can be done now is so much gain of time. Unless it be the dwarf variety of *Salvia splendens*, which must be propagated from cuttings to keep it even in growth and in time of blooming, plants of *Salvia* may be raised from seed with less trouble. *Solanum capsicastrum*, otherwise known as the Jerusalem Cherry, although a native of Brazil, is a very ornamental berry-bearing plant. Seeds should be sown early to have the plants make a good setting outdoors before autumn. We have a good strain, which always comes true. Much of the store seed is mixed, and therefore many growers select a well-berried and neatly bushy plant for propagating by means of cuttings. The seeds should be put in now. Seeds of *Dracæna australis* come quite freely, and when sown early and planted out in rich soil, under good culture, they make neat plants for winter decoration. The following season we use them for subtropical gardening, and afterward throw all but a few of the best away, having meanwhile raised a new lot. *Grevillea robusta* we treat in the same way. One-year-old plants are exceedingly pretty, averaging from one to two feet in height. They come in handy the following season for bedding purposes, and as centre plants nothing is more graceful. *Eucalyptus globulus* is another of this class, but its usefulness usually ends with one season. It may be used the following winter for grouping, where its blue-green leaves have a striking effect, but it loses its leaves badly and soon becomes unsightly. Seed of single *Dahlias* should be sown early to have bloom in good season. *Mirabilis Jalapa*, Marvel of Peru, is an exceedingly showy border plant. That it is common, or once was, should be nothing against it. A month or six weeks may be gained by sowing the seeds now. *Maurandya Barclayana* is a pretty little climber, and an equally beautiful plant for gracing the edges of vases and of hanging baskets, where there is plenty of sunshine. Its large Pentstemon-like flowers of violet and white are exceedingly pretty. The showy perennial, *Gaillardia grandiflora*, is more satisfactory when treated as an annual sown early. The single forms of *Pyrethrum roseum* make splendid border plants and are among the most useful for cutting. In the Old Country large collections of named varieties, mostly double, are kept up. The climate there is more favorable than ours, and they grow readily. They stand our winters better than the summers, and usually die out after a year or two. A continuous display of the single forms is maintained more easily by sowing a lot every spring. Those who like the perennial *Lupines* will be pleased with some of the annual kinds. *Lupinus nanus* is low-growing and pretty. *Lobelia cardinalis* and *L. fulgens* *Victoria* bloom abundantly all through the autumn from spring-sown seed. These handsome plants naturally grow in wet soils, but we have had them do quite well in dry positions. *Campanula Carpathica* blooms abundantly from July onwards, when sown early, as do *Larkspurs*, *Antirrhinums*, *Pentstemons* and *Violas*.

At the place of H. H. Hunnewell, Esq., there are several small bushy specimens of *Bougainvillea Sanderiana*. This handsome novelty resembles, in the color, shape and arrangement of its flowers, the older *B. glabra*, and like it has a more continuous period of bloom than the still older and coarser *B. spectabilis*. Though quite as spiny as *B. spectabilis*, it is in no sense a climber. The habit is erect; the plant is short-jointed and blooms on the ends of all the shoots. Mr. Harris trimmed off the side shoots from one plant, with the intention of making a standard of it. Fresh shoots appeared all along the stem, and each one was full of bloom, although but a few inches in length. The *Socotrana* hybrid *Begonia*, *Gloire de Lorraine*, noted five weeks ago, is still in perfect bloom. It is, without doubt, the loveliest winter-flowering *Begonia* ever raised. *Clematis indivisa* promises to be better than ever this season. It will cover nearly four hundred square feet of the roof. No better place could be found for this handsome winter-flowering *Clematis* from the antipodes. It has a cool place in summer, quite free from the stimulating effects of

bright sunshine in the orangery, facing north-west. The flower-buds are now showing, and in the course of a month it will be worth going a long way to see. The conservatories are gay with Cinerarias, Cyclamens, Primulas, Cytisus racemosus and C. elegans, Eupatoriums, Antirrhinums, Coreopsis Drummondii, Euphorbia fulgens and E. pulcherrima, Lantanas, Impatiens Sultanii, Statice Holfordi, Freesias, Libonias and many other plants. Daphne Indica, Begonia nitida, Freesias, Mignonette and Violets emit a pleasant perfume.

Wellesley, Mass.

T. D. Hatfield.

### Garden Phlox.

THE varieties of garden Phlox are doubtless more useful for summer decoration than any other one class of plants. They are in bloom for three to four months of the year, and few hardy border plants give as much satisfaction for the little care required. Perhaps the slight attention they need is a drawback to their cultivation, as the general impression is that it is only necessary to set out the plants and the work is done. There could not be a greater mistake made with regard to garden Phlox, or, indeed, any other garden plant of value, and only such plants as Dandelion and Purslane take care of themselves.

All highly developed plants, such as Phlox, Double Pyrethrum and Larkspur, are the result of rigid selection and attention, and the tendency is to revert or degenerate to original types. How often when passing a neglected wayside garden do we see near the fence a few Tiger Lilies, a clump of Pæony, and almost inevitably a few tall stems of the old purple Phlox. If the latter is closely examined it will be found to be almost identical with *P. paniculata*, from which all of this class sprang. No matter how intricate the pathway up to the florist's standard of a good type of garden flower, it is only a step or two back to original principles, and any one who grows such plants in the garden knows that it is more trouble to weed out these reversions each year than to eradicate true weeds. The highly developed varieties of garden plants must be nursed and fed according to their needs. Phlox is a great feeder and requires a constant supply of rich food to keep it in good health. A strong clump will die out, not at once, perhaps, but in a season or two, simply from lack of nourishment. Before it dies an abundance of seed will have been scattered, and the weaker the parent plant, the greater the proportion of fertile seeds, for this is nature's method of perpetuating its kind. The result the next year is a quantity of degenerates in the border, and sometimes there is a tendency of the original plant to revert.

There are three well marked divisions of border Phlox. One has *P. suffruticosa* as its parent, and is not so often in evidence as the other two that owe allegiance to *P. paniculata*. From this species there are two sections, one early-flowering and dwarf, and the other is taller and flowers late in summer. These two last named are the ones of most value, from which we have the best forms with brightest colors. There is not much to choose between the productions of Lemoine in France and Kelway in England. Lemoine was the pioneer in this, as in other great advances with garden plants, while Kelway has carried on the work and done much to distribute his plants. A list of the best sorts is scarcely needed here, and would be a repetition of lists already published.

The longevity of these plants depends on their propagation. If only a few reserve plants are needed to keep up the supply, the clumps should be lifted in spring as soon as frost will permit. They should be divided carefully and the pieces replanted in fresh soil. If a larger number is required, the clumps should be placed in a warm greenhouse or hot-bed until they send up young shoots. These should be taken off as soon as long enough, when they will root freely. If grown in pots and hardened off they may be set outdoors in early summer, and they will flower freely at the proper time. Only one large head will be produced the first year, but thereafter the roots will increase rapidly. If a quantity of summer decorative plants in pots are required, some may be kept and grown on in pots, giving them a shift as they need it, and few plants will give greater color-effects than good garden Phlox grown in this way. It is also possible to prolong the season of flowering by taking off the flower-head as soon as it appears. The dormant side-shoots will then develop, and the display will be equally good, but later.

Like many other of our best garden plants, these are purely North American. The original species was found here, but was developed in Europe, as were Pentstemons, and more recently the common wayside Aster. The latter are fertile in good forms of garden origin, but these do not seem to have yet recrossed the Atlantic.

South Lancaster, Mass.

E. O. Orpet.

**Seedling Orchids.**—We have had in flower here for six weeks past a seedling *Cattleya*, a hybrid between *C. intermedia* and *C. Mossiae*. The flowers are much larger and in every way a decided improvement on those of *C. intermedia*, the sepals and petals being a delicate light rose, and the labellum blotched with purple and yellow extending well up into the throat. The pseudo-bulbs are nearly a foot long, with two large dark green coriaceous leaves at the apex. A robust-growing *Cypripedium* now flowering is a seedling of *C. Ashburtoniae* and *C. Curtisii*. It has flowers as often as three times a year. It has a large dorsal sepal with a deep band of white which ends with a shading of light green. The petals are shaded light purple with numerous spots, and the dark hairs extend the entire length on both the upper and lower margins. The pouch is large and reddish brown, and altogether it seems to be an admirable plant to breed from. Another is a seedling of *C. Javanicum* crossed with *C. ciliolare*, a strong grower, producing two flowers on a stem, large dorsal sepal white with light rose-colored veins, petals light green spotted, and a pouch light red. We have several seedlings of *C. speciosum* crossed with other species and varieties, many of them in flower and others coming on, and although we have none which present any decided improvements either in richness of coloring or grace of form, they amply repay all our trouble, and we are assured that any one with even a small collection of Orchids can derive a great deal of profit and pleasure by crossing them and raising seedlings.

### Correspondence.

#### Orange Groves as an Investment.

To the Editor of GARDEN AND FOREST:

Sir,—Mass meetings are now being held throughout California to ask Congress for increased duties upon importations of such foreign-grown fruits as compete with those grown in this country. Among the most interesting facts brought out during the discussions is a careful and exact estimate by an experienced orange grower of the cost of the high-class Orange groves in the San Bernardino valley and adjacent districts, which are now producing the fancy fruit that commands the highest price, and of the annual product which may be expected from those groves. I have never seen such candid figures upon this subject in print, and they may be of interest to some of your readers.

The initial cost of these groves was \$250 an acre for the land, \$100 an acre for the water-rights, \$50 for grading and preparing to plant the trees, \$100 an acre for the young trees and \$50 for the planting and staking, making the capital invested at the outset \$550 an acre. The use of money in California costs ten per cent. per annum, and interest should therefore be figured at that rate. The care of a grove costs, on an average, \$20 an acre yearly. There are assessments upon the water stock, to pay the expenses of caring for the plant and of delivering the water to consumers, amounting to \$4 an acre annually. With these expenses each year the investment amounts to \$629 at the beginning of the second year, \$715.90 at the beginning of the third year and \$811.50 the fourth year. At the end of the fourth year \$20 may be deducted as the value of ten boxes of oranges; \$50 may be deducted the fifth year for twenty-five boxes, and \$100 the sixth year for fifty boxes. Adding the expenses as above and deducting these amounts, the net cost at the commencement of the seventh year is \$980 an acre. The expenses of interest, etc., during this year amount to \$122, and a yield of 100 boxes may be expected, worth \$200, net, thus leaving a profit of \$78 above expenses the seventh year.

In this estimate taxes are not considered, because they vary with location and other conditions. But it is safe to assume that the taxes for the seven years will wipe out the profit of the seventh year and add \$20 to the cost of the grove, thus making the cost at the commencement of the eighth year an even \$1,000. The production from this time on increases rapidly, until, in the tenth year, it should amount to 300 boxes an acre, worth, at present prices, from \$450 to \$600, and giving a net return of from \$350 to \$450, or about forty per cent. upon the investment. These figures are estimated upon the cost of a Navel Orange grove, but the average seedling grove will probably bring equal returns, because it will bear more fruit, although it will be two or three years longer in coming into full bearing.

While many groves, even in favored districts, do not produce the above amount of fruit, that product may now be rendered almost a mathematical certainty by following ap-

proved methods of planting and care determined after long and expensive experience, which pioneers in the industry lacked. The details of preparing the ground, selecting the nursery stock, pruning, cultivating and fertilizing are all important. For instance, many growers heretofore have headed their trees at least four feet above the ground, simply because a tree of that shape looked better to them. But it has been proved that trees which are allowed to branch only a foot or eighteen inches above the ground produce much more fruit, especially in the early years. The Orange-tree begins to bear near the ground; as it grows older the upper branches become stronger and gradually put forth fruit, and the new growth of this year bears oranges next year. Therefore a tree should be headed low and given as many strong limbs as it will carry, with care in preserving new wood and in pruning, so that sufficient light and air may penetrate the foliage to mature the fruit on the inner branches. The more skillfully it is pruned the nearer will the tree finally approximate to the ideal of bearing oranges from top to bottom the entire length of the branches. The use of suitable commercial fertilizers, even on young orchards, is repaid by many times its cost, yet it has been taken for granted by many inexperienced planters that the virgin soil of southern California, which is principally decomposed granite from the mountain ranges, requires no fertilizing whatever for many years. Inexperience and misconceptions in these matters have frequently caused disappointment in the yield of bearing groves.

Many people who plant orchards with an imperfect understanding of these conditions and, perhaps, with purses too light to stand the strain of such incessant and long-continued demands grow weary of the struggle and offer their properties for sale below their cost. Good orchards in favored locations, from four to six years of age, may be had to-day at from \$500 to \$800 an acre. Many growers, too, commence without an understanding of the competition which they are likely to meet, and later become alarmed when they read about the millions of Orange and Lemon trees that have been planted in southern California.

These are the prices of the best groves, in a few of the districts which have the greatest natural advantages, such as freedom from frost and certainty of water supply. They were based, perhaps, too largely upon the prices obtained for oranges several years ago when the total product of the state was only a few hundred car-loads, and they should now be revised with reference to the fact that southern California now has a million and a quarter Orange-trees in bearing, and a million and three-quarters planted but not yet in bearing, with a quarter of a million Lemon-trees in bearing, and a million planted and coming into bearing. This makes the astounding total of four and a quarter million Citrus-trees of these two kinds which will soon be producing, an increase which the wildest boomer of six years ago would not have predicted. Competition will doubtless bring down the price of oranges, and consequently the value of the groves. There will be an increasing competition from the groves of Florida. It is an open question whether these groves will be worth as much five years from now as they are worth to-day.

The nearly half a million acres of Citrus fruits in southern California represent investments of probably \$35,000,000, and the holders of these properties think that they are now important enough to be worth protecting. The amount of protection which will be asked for has not been decided, but it will not be less than fifty cents upon each box of oranges, lemons or limes holding two cubic feet, and an equal rate upon these fruits by weight or bulk in other packages. The fruit industries of northern California, which run more largely to canned and dried fruits, will have similar requests to make. The outcome will be awaited with anxiety by a little army of fruit growers in all parts of the Golden state.

William M. Tisdale.

### Need of Instruction in Experimental Plant Physiology.

To the Editor of GARDEN AND FOREST:

Sir,—In making up the report of the section on horticulture and botany for the recent meeting of the Association of American Agricultural Colleges and Experiment Stations, one of the questions asked, in a circular letter sent out to the horticulturists and botanists of the various states, was, "What attempt is made to teach experimental plant physiology?" The replies indicate that in more than half of the institutions heard from little or nothing is being done along this line. This, of course, does not mean that there is no incidental class-room instruction or mention of topics falling under this head, but it does

mean that no course is offered in which the student makes it his especial aim to get at the functions of plants by means of experiments carried on by himself. In the report made before the Association this matter was emphasized, and it was urged that this subject ought to be pushed to the front and so arranged that students who expect to deal with living plants should have the opportunity to get instruction in such matters.

Without any knowledge of this report of the chairman, Dr. G. E. Stone, of Massachusetts, presented a strong paper, in which he emphasized the importance of the same subject. The term plant physiology is one which has been vaguely used, and Dr. Stone called attention to the limits which should be placed around it. As commonly accepted, plant physiology embraces the following subdivisions: (1) Nutrition; (2) Growth; (3) Physics of vegetation; (4) Plant movements; (5) Reproduction. The latter subject manifestly occupies a somewhat different position from the others and is now being given over to the domain of ecology. It is evident that in the subjects of nutrition, growth and physics of vegetation, which include the relations of the plant to heat, light, moisture, etc., we deal with problems of the greatest practical moment to the horticulturist. The discussion which followed the paper above mentioned showed that the horticulturists present appreciated this fact and were anxious to secure better training for their students along such lines, and some of them have tried to supply such teaching themselves. To urge the need of such knowledge to the horticulturist when his success or failure depends upon his being able to aid the plant in carrying on these functions, or to provide it with such surroundings as will enable it best to do this, seems superfluous. Yet little attention has been given to this kind of instruction, and least of all to the particular class of students who are most in need of it. If these things are essential to the commercial horticulturist, how much more are they needed by the horticultural teacher and experimenter? Scarcely an experiment connected with practical cultural problems can be completed without coming in contact with just these questions which it is the province of physiological botany to elucidate. In order to put this statement to a practical test I turned to the outline of our own horticultural experiments for the past season, and ran over the topics there represented. Thirty of these would either directly or indirectly deal with questions falling within the domain of plant physiology, while sixteen apparently would not, although even here it would not be surprising to find such problems creeping in at unexpected places. The value of this work, therefore, cannot be questioned, and the botanists will, no doubt, stand ready to do their part if they but recognize that there is a real demand and need for such instruction. Let me here emphasize the word experimental, as connected with the title. To be of real value to the student he must prove all things as he goes. He must not merely take the statement that things are so, nor stand by and see the professor prove that they are so. This, of course, means study and thought on the part of the teacher, and it also means apparatus and expense, but the results will justify the cost. In order that the work shall be of most value it is evident that the student should have had some previous instruction in other lines of botany, yet this may not be absolutely essential, and if it is possible that instruction can be arranged which is so simple that it can be followed with profit by the farm boy who comes but for a hasty sip of knowledge during the midwinter months, much will be gained. I fear that many horticulturists, like myself, feel the need of these things more from want than from the possession of them. Many desirable things must be omitted from every education, but is it not reasonable to believe that a knowledge of the functions of life of the few plants with which he deals is of greater importance to the horticulturist than a knowledge of the name and classification of the many plants which he seldom or never sees?

### Chrysanthemums Out-of-doors.

To the Editor of GARDEN AND FOREST:

Sir,—I note in your issue of December 9th the record of an attempt by one of your correspondents to mass Chrysanthemums as a feature of landscape-gardening. This is not an easy problem, because the Chrysanthemum flower is so large and conspicuous. If we mass dozens of the same colors, attempts to blend them agreeably are futile, because the quantity of each color is too overpowering. The shrubs mentioned by your correspondent as bearing bright berries and growing among the Chrysanthemums, and shrubs retaining foliage very late, would make the best material for uniting them, and

perhaps a better result would be obtained if the order were reversed, Chrysanthemums used to connect the shrubs—that is, mass the shrubbery somewhat and let Chrysanthemums come up in an unstudied way, without much arrangement, between the groups and sometimes among them as to colors.

A few years ago a load of rubbish from the flower garden—dried stems of Hollyhock, Zinnia and Calliopsis—was dumped upon a strip of ground in the rear of some outbuildings. A little later this was burned and the ground plowed. For some reason this bit of ground was not needed and received no cultivation. In due time it bore a fine crop of grasses and weeds, but by summer-time the flowering plants asserted themselves and presented a dazzling mixture of almost every conceivable color, yet it was never perplexing or tiresome to the eye. The blossoms of Zinnia are all the time changing as they advance toward maturity. In this case none of the flowering plants attained very large size; they grew with the grasses and weeds, many of the latter outgrowing the flowers a little and making, with the various kinds of grasses, a perfect blending of color. This impromptu flower-bed never failed to produce a most pleasurable surprise when one had to pass in sight of it. This wild flower-bed leads me to suggest that if Chrysanthemums were planted among and between groups of shrubbery—and without arrangement—as if they had come up spontaneously, they might be effective out-of-doors.

Paul Le Hardy.

### The Palmetto Scale.

To the Editor of GARDEN AND FOREST:

Sir,—In 1883 Professor Comstock described a new species, *Aspidiotus sabalis*, found on leaves of Palmetto in Florida. The species is very peculiar, and has lately been made the type of a new genus (*Comstockiella*). Up to the present time it had never been observed on the Pacific coast; but Mr. Alexander Craw, the horticultural quarantine officer of California, has just sent me specimens on leaves of Palms from Mexico which had been brought to the port of San Francisco on November 17th. The scale was new to Mr. Craw, but he wisely had the Palms destroyed, so as to avoid all possibility of the introduction of the creature into California. Mr. Craw thinks the Palms came from near Mazatlan, and were growing wild about seventy-five or one hundred miles inland.

This scale should be looked out for by importers of Palms. It is about the size and shape of a pin's head, pure snow-white, without any yellow or black spot. The male scales are similar in color, but smaller and elongated. Mr. Craw's Mexican specimens represent a variety (*v. Mexicana*) distinguished from the Florida form by the female (under the scale) being orange-yellow, and the ventral grouped glands numbering, caudolaterals 14 to 17, mediolaterals 11 to 15, cephalolaterals 7 to 10, the respective numbers for the type (from Florida) being 6 to 10, 4 to 7, and 4. But these are microscopical details, and for horticultural purposes it is probable that the two forms may be treated as one.

Mesilla, N. M.

T. D. A. Cockerell.

### Recent Publications.

Under the direction of the Department of Agriculture, Dr. Erwin S. Smith has prepared a bulletin relating to *A Bacterial Disease of Tomatoes, Eggplants and Irish Potatoes*, besides other members of the same family. This bacillus was first brought to notice by Dr. Halsted, who considered it identical with the micro-organism which causes the Bacterial Wilt in Cucumbers and Canteloupes. But microscopic examination of infected Tomato-stems from Mississippi showed that they swarmed with bacteria of a different kind. Healthy Tomato and Potato plants were inoculated with pure cultures of this bacillus, and they rapidly succumbed to the disease and became ultimately a mass of disorganized and ill-smelling slime. As it appears in the field the farmer first detects the malady by the sudden wilting of the foliage of his plants. In the case of the Potato the tubers are ultimately attacked and destroyed. In southern Mississippi the losses of the Tomato crop have amounted to thousands of dollars. Indeed, the disease has been so destructive in many places that entire fields have been destroyed year after year, so that the cultivation of this crop for market has been abandoned. About Charleston, South Carolina, whole fields of Tomatoes and Eggplants have been destroyed and the early

Potato crop seriously injured. Many of the tubers that appeared sound on digging rotted on the way to market. It is not a new disease, and it certainly occurs as far north as New York, and probably it has been confounded with other diseases of the Potato and Tomato, for it is unquestionably true that only a small part of the so-called Potato-rot is due to the well-known Potato-mildew, *Phytophthora infestans*. How serious this matter is can be imagined when it is estimated that the loss to the potato crop in a single year from the rot has exceeded 50,000,000 bushels.

An interesting fact brought out in this bulletin is that the Colorado potato beetle is prominent as an agent in distributing this disease, as experiments in the greenhouses of Dr. Smith have clearly demonstrated. The direct injury from bites and punctures is not the only one inflicted by the beetles, and often not the worst one. Given one diseased plant in a field and plenty of insects to feed upon it, and the transmission of the infection to all parts of the field, and thence to the whole neighborhood, is only a question of a few weeks. No experiments have been made with other insects, but it is possible that flea beetles, blister beetles and many other species which feed on leaves may act as carriers of the virus. Of course, this gives an added reason for the prompt destruction of the leaf-eating and leaf-puncturing insects. Another preventive measure is the destruction of diseased plants, a precaution which should be begun early in the season. When the disease has become widespread among Tomatoes and Eggplants there is no help for it. In the case of potatoes a considerable part of the tubers may be saved if they are dug before the vines have shriveled and stored in a dry place. Since this organism may probably live over winter in the soil of the Potato and Tomato fields, it is a good precautionary measure to plant Tomatoes, Eggplants and Potatoes in new ground, or at least in land where neither of these crops has been raised for several years. It is also safer to select seed and tubers from plants grown where this disease does not prevail. Altogether, this little bulletin, No. 12, from the Division of Vegetable Physiology and Pathology, although it only occupies twenty-five pages, is a most interesting and instructive monograph. It has half-tone pictures of healthy and infected plants of Potato and Tomato, and a colored plate illustrating the brown rot of the Potato, *Bacillus Solanacearum*, n. sp. Students of vegetable pathology will be glad to find a table of contrasting characters which points out the differences between *Bacillus Solanacearum* and *B. tracheiphilus*, the organism which causes the Cucumber Wilt; and another table, showing the difference between the *Bacillus Solanacearum* and the bacillus producing the Potato rot described by Dr. Ernst Kramer, without name, in 1891.

### Notes.

Forty years ago the annual import of oranges into England did not exceed 40,000 cases, while during the last year three million cases were put on the English market.

Unusually large quantities of cocoanuts have been imported recently, and in December 1,174,000 were received at this port from Porto Rico and other West Indian islands.

A pure white sport of the pink Carnation, William Scott, is now being raised in some quantity by Mr. John Harrison, of Jersey City, under the name of Harrison's White. It promises to be a valuable commercial variety.

A Boston correspondent of *The American Florist* states that branches of the California Pepper Tree, *Schinus molle*, has lately been received in good condition in that city from California. It is suggested that the long drooping branches of this tree, with its graceful pinnate foliage and deep pink berries, would make a good addition to the material used for decorative purposes at Christmas.

A correspondent makes inquiry for a good application for covering the wounds of trees where large limbs have been cut away. For the treatment of trees on a large scale we know of nothing better than an application of coal tar, which is sufficient to exclude the air and the germs of destructive fungi. In a recent number of *The Rural New-Yorker* several prominent orchard-

ists recommend good grafting wax as the best application for wounds of Apple-trees where large branches have been removed. This should be applied as soon as possible after the amputation, and it should be pressed closely to the surface, where it will remain sometimes three or four years. Gum shellac, such as painters use for covering knots, is good, but it needs to be renewed the second year.

The vegetable known as Chocho or Chow Chow, and occasionally seen in the New York markets, is said by *The Gardeners' Chronicle* to have become more generally known and used in London, last year, than it ever before has been, so that it forms a part of the stock of greengrocers in almost every town of considerable size in England. *Sechium edule* belongs to the Gourd family and is a perennial which will grow in our southern states. Both the fruit and the large tuberous root make excellent food for animals, while the plant itself is a quick-growing climber, useful for training over fences to hide unsightly objects. Inasmuch as the fruit is picked before it is ripe it can be transported safely from the West Indies, and since it is said to be very palatable as well as nutritious its speedy introduction as a regular market vegetable in this city ought to be looked for as certain.

The Endive is usually esteemed as a salad plant, but some people consider it too bitter for that purpose, and Professor Waugh states in a late bulletin that it makes most excellent greens when cooked. The variety known as the Ever White Curled does not run quickly to seed, and when blanched like Celery or Cos Lettuce by tying up the leaves or drawing the soil up about the plant it makes an attractive salad plant. For eating cooked, however, it is best to take the plants when very young before they have time to make heads and when they are in their tenderest stage. The seed can be sown early in cold frames or in the open ground like Lettuce, and, of course, plants can be grown in from forty to fifty days at any time during the summer, but in the very hottest weather they are not of the best quality. Autumn-grown plants can be taken up with some earth adhering to the roots and stored in a dry cellar or in a cold frame for winter use.

White, red and yellow onions of many qualities are now in market, from Cuba, Bermuda, Spain and different sections of this country. Among fresh vegetables recently come into season are beets, from Florida. Other receipts from this state are tomatoes, string-beans, peas and eggplants, all of which are too abundant in inferior grades, while choice stock is scarce. Lettuce from the same section, peppers, cymplings, or scalloped squashes, and cucumbers are of fair quality. Besides domestic cabbage, some is imported from Denmark. Kale and spinach, from Virginia, are plentiful, and much of it in poor condition, so that the prices realized here do not cover the cost of freight. Only exceptionally good lots of spinach realize as much as \$1.00 a barrel in the wholesale markets. Cauliflower is now arriving from California and from near-by places. Parsnips, carrots, celery, pumpkins, Marrow and Hubbard squashes, turnips, from Canada and from neighboring states, are among the staple winter vegetables, with sweet potatoes from southern New Jersey, and potatoes from Bermuda, Maine, Michigan and New York.

The receipts of Jamaica oranges have been gradually falling off, 2,900 barrels arriving during last week. Altogether, 237,530 barrels of this fruit have been sold here this season, while in the same period a year ago the importations amounted to but 194,496 barrels. These oranges come in barrels, and are assorted and repacked here in boxes similar to those used in Florida. Seven dollars a barrel is the highest wholesale price for sound fruit at this time, and \$3.00 for a box. The experiment was made several weeks ago of sending 2,000 boxes to England, but, while the oranges were in good condition on landing, they spoiled quickly when unpacked, and were sold at a loss. The trade in oranges is usually dull after the midwinter holidays, but those from Florida and Jamaica have advanced in price during the past ten days. The demand is for the sweet fruit, and the tart Mediterranean oranges have declined. Bright grape-fruit, from Florida, commands \$8.00 to \$10.00 a barrel in wholesale lots; that of russet color, \$5.00 to \$6.00, and the best from Jamaica, \$5.00 to \$7.00. Tangerines, from California, cost \$5.00 to \$6.00 a box, and those from Florida sell for double this price. Only limited quantities of lemons are coming from Sicily; wholesale prices range from \$1.00 to \$3.00 a box, an advance of twenty-five cents during the past week. The lemon crop in southern California for the year beginning November 1st, 1896, is estimated at 1,000 car-loads.

Mr. Felix Gillett, in writing to the *Pacific Rural Press* on the subject of Chestnut-growing in California, says that he can graft European Chestnut-trees successfully at any time between the first of March and the first of October. His experience is that the best varieties of the European Chestnut, or Marron, will flourish well in the central and northern part of that state. Being a mountain tree, it flourishes in gorges with a sunny exposure in Nevada County up to an altitude of 3,000 feet, where trees twenty-five years old are now bearing marrons of excellent quality and in such abundance that Thanksgiving turkey stuffed with chestnuts is quite the fashion in that region. If half the territory of California is well adapted to the cultivation of Marrons, it would seem that another important product may be added to what can be raised in that state. A tree planted in the spring of 1871 by Mr. Gillett now averages ninety pounds of nuts a year, which he can sell for fifteen cents a pound, and the tree bears crops every year. When it is remembered that Paris alone consumes 20,000,000 pounds of marrons, or dessert chestnuts, a year, and that Italy alone produces 500,000,000 pounds, one can see how important this trade is in the countries of southern Europe, where the Chestnut is called the Bread-tree, being so valuable as a food for men, and in seasons of abundant yield even for animals.

We are glad to observe that Mr. T. V. Munson, in writing for *The Park and Cemetery* of woody vines, speaks of various species of the Greenbriers (*Smilax*) as especially useful on account of the freshness and beauty of their foliage. We have frequently called attention to the rare value of these native plants, especially wherever a screen of foliage is needed. Mr. Munson also does justice to another class of native climbing plants in advocating our Grapevines for decorative use. *Vitis cordifolia*, *V. rubra*, *V. cineria* and *V. riparia* can easily, he says, endure a temperature from fifteen to twenty degrees below zero, and they are much more beautiful than many of the climbing plants used in parks and gardens, but if nurserymen keep these native species in stock they never advertise them. The Fox Grape, *V. labrusca*, and the Summer Grape, *V. æstivalis*, Mr. Munson considers too coarse and rigid for most positions, although they often make beautiful vines. He regards *V. Munsoniana* as the finest ornamental woody vine known for the Gulf states, a species nearly related to the common Muscadine, which is much coarser. *V. Munsoniana* is a rampant grower, but slender and graceful, with small, smooth, shining toothed leaves which become a fine scarlet and crimson late in autumn. This plant will endure any amount of heat and drought, and it will survive a winter temperature of five degrees below zero. Staminate plants of Grapevines should be used for park planting, as the fruiting vines would likely be torn by boys in their raids on the grape clusters.

The *Monthly Weather Review* quotes from a memoir of Messrs. Petermann & Graftiau, published by the Academy of Sciences in Belgium, in which it is demonstrated that hoarfrost is particularly rich in nitrogenous compounds, and therefore plays an important part in adding to the stock of nitrogenous matter in the forest as well as to the purifying influence that forests exercise on atmospheric air. The frost-work attached to the branches of trees, being continually renewed, presents to the air a large surface for the absorption of all soluble matter that it carries, so that single trees and forests act like immense filters, purifying the air that circulates through them, and collecting from it nitrogenous combinations, which, being returned to the soil by a thaw, serve again as nutriment to plants, and thus reënter the vital cycle. The amount of frost which the branches hold is often much greater than their own weight, and in a measured cube which touched the extremities of the branches of a given shrub the weight of the frost-work which they held exceeded one kilogram for each cubic metre of space. Carrying out this calculation to a forest area, it is quite possible that seven pounds of nitrogen are deposited on every acre during a severe frost. When frosts are formed to such an extent as to break branches by its own weight, the quantity of nitrogen given to the soil must be very considerable. It is held, therefore, with good reason, that the frost represents a very appreciable factor in collecting the reserve of nitrogen within forest areas, and if we add to this the nitrogen contained in the rain, the dew and the fog, we can explain why, without any addition of this material, or without the intervention of those plants which collect it directly from the atmosphere, the forest vegetation is well supplied with nitrogen. These facts also show how the soil of forest areas grows richer in this element which is given to it by the detritus, or waste of woodlands.

## The North Woods.

IT is now twenty-five years since the passage of an act by the Legislature of New York providing for the appointment of seven Commissioners of Parks for the state, who were directed to inquire into the expediency of "providing for vesting in the state the title to the timbered regions lying within the counties of Lewis, Essex, Clinton, Franklin, St. Lawrence, Herkimer and Hamilton, and converting the same into a public park." That is, as long ago as 1872 there was a general recognition of the value of this region for its timber-supply, for its usefulness in preserving and maintaining the water-supply of the canals and streams of the state, for furnishing hydraulic power, and for the attraction which its picturesque scenery, its numerous lakes and its abundant game offered to the invalid, the tourist and the sportsman. This record also demonstrates that even then the attacks on the timber of this vast region had been so merciless that the Legislature had been driven to take some active interest in its preservation. In the documents prepared by these commissioners, of whom the Hon. Horatio Seymour was President, it is set forth that this broad area, once owned by the state, had been largely conveyed to purchasers who had bought it for the timber and bark it carried; that a single tract embracing more than a quarter of a million of acres had been conveyed to a corporation for five cents an acre under a scheme of speculation that was little less than fraudulent, and that the state then owned but a small fraction of the territory, and this was in detached parcels. The report also declares that the lands originally bought for their timber had been largely abandoned after this was removed as not being worth to the holders the taxes on wild lands, so that large blocks had been repeatedly sold for arrears of taxes or left in the possession of the state as not worth these claims until, in the course of time, another growth had made them desirable, when they were again bought from the state, again to be abandoned when stripped of everything worth carrying away. It was stated also that whenever a project for repurchasing this land was brought forward the owners would combine to raise the price to an unreasonable amount, so that Dr. Hough, another of the commissioners, stated two or three years

later, in a Congressional document, that "insuperable difficulties toward establishing this park were found in the fact that the soil belonged chiefly to private owners, and could not be acquired without unreasonable cost."

And now, twenty-five years later, Governor Black, in his first annual message, pronounces these words of warning and reproof: "A question too long neglected is the preservation of our forests. The state, either through indifference or false economy, has been stripped of its most valuable timber lands, has allowed its water-supply to be seriously impaired, and the most wonderful sanitarium of the world to be defaced and partially destroyed. Every element of economy and foresight is outraged by this course." And he goes on to say that private individuals, taking advantage of the state's neglect, have taken possession of more than three-fourths of the area of the entire Adirondack region, and that more than five-sevenths of the proposed Adirondack Park, which includes some 2,800,000 acres, are now held as private preserves or owned by lumbermen, much of the land being exposed to appalling and disgraceful devastation by fire and axe. When we remember that during all these years the destruction of these forests has been the theme of public discussion in the press and of reports by commission after commission, and that it has furnished matter for legislative oratory and action at every session, the result can hardly be pronounced encouraging. The report of Mr. Seymour's Commission stated that the ruin was going on unchecked, and it has been going on ever since. It seemed to the early commissioners that the land could not be acquired without unreasonable cost to the state, and it will cost the state ten times as much to-day. But something has been gained. A constitutional amendment has been adopted which, in a blind, uncivilized way, attempts to save the forests on the state lands by forbidding anybody to use them. Of course, neither state forests nor any other forests can have any direct economical value unless their products are gathered any more than a farm can be made profitable under a prohibition against harvesting any crops. The exclusion of the axe from the state woodlands, provided they are not devastated by fire or water, does, however, give them a certain assured value as a protecting cover to the land, and the people of the state showed that they were in earnest in preserving this bulwark against destruction of our state forests when they voted almost unanimously at the late election against nullifying or changing the constitutional provision. Another cheering symptom is found in the vigorous words of the new Governor, which prove that he has given some personal thought to the matter, for no more convincing statement as to the need of the preservation of these forests can be found in any public document. Following the words already quoted, Governor Black says:

More than four hundred and fifty million feet of wood and timber are cut, and more than one hundred thousand acres are stripped every year. This work of devastation is progressing fast. The banks of the lakes and rivers, and all sections accessible from either, are ravaged at such a pace that but few years more can elapse before that region, in many respects the most wonderful and valuable in the world, will be practically destroyed. The parts acquired or claimed by individuals are the best. A traveler through any desirable portion of that country is sure to be met with the charge of trespassing, for the cases are rare in which the title of the state to a desirable tract is acknowledged. Some time this deplorable condition must be rectified. Every year the loss to the state grows larger, in all cases difficult, and in some cases impossible, of recovery. The land is steadily and rapidly increasing in value. The bogus title burrows further out of sight the longer it is let alone. Witnesses die, and the only thing sure to increase is the encroachment of individuals upon the domain of the state. The enlargement of the canals will require more water, and the demand in every direction is increasing, while the supply is steadily falling off. A subject of such magnitude should not be postponed, nor conducted with the halting method which is too apt to distinguish public enterprises, in which large appropriations afford convenient resting-places in which office-

holders may grow old. Not long ago the state appropriated a million dollars to preserve the beauties of Niagara Falls. That subject is without significance compared to the Adirondack forests. Every consideration of health, pleasure, economy and safety urges the speedy consideration of this subject, and such consideration should include appropriations adequate to ascertain the nature of the titles adverse to the state, to recover where the titles are insufficient, and to purchase where they are valid. Any other course would be false and unwise economy.

It will be observed that the Governor has come to a point which his predecessors should have reached long ago. Commissions and reports and constitutional restrictions will be unavailing so long as the greater part of this region remains in private hands. The first thing needed is money to secure these lands forever for the state. This is the only salvation of the Adirondack forests. The sooner these lands are acquired by the state in fee simple the better. The cost alarmed commissioners twenty-five years ago, but we can all now see that the state would have made a wise investment if it had purchased every acre then. The land will cost more to-day, and many times as much twenty-five years hence; but in the end the state must own the North Woods, if there are any woods to own, so that every dictate of wisdom suggests that their devastation should be arrested at the earliest possible moment.

### Two Years After the Great Freeze in Florida.

THE cold wave which swept over Florida in December of 1894 and February, 1895, left the orange growers of that region almost stunned by the calamity, but they were so ignorant at the time of the real damage accomplished, and there was so little information to be obtained from those who had passed through a like experience, that they were at a loss what to do in order to recover from the effects in the shortest time. Mr. H. S. Williams, a prominent orange grower of Rockledge, has therefore written for the *Indian River Advocate* a careful and minute account of the calamity, which is of great value from an historical point of view, and to this he has added some advice, based on experience, which will be useful in case the orange growers of Florida should ever again suffer from such a disaster. The whole article is of interest, even to the general reader, but our available space compels us to condense it materially.

Friday, the 28th of December, 1894, was a raw, disagreeable day, with heavy westerly winds, but there was nothing in the conditions to threaten severe frost. At sunset the thermometer stood at thirty-six, and the five o'clock mail brought word that the temperature would fall to twenty-five degrees in the northern part of the state. These figures did not indicate a destructive cold wave, but if the information had given the real temperature at Jacksonville, which was fourteen degrees, the information would have been useful. However, the record of my thermometer, together with the report from Jacksonville, satisfied me that the orange crop of the year was lost. At the break of day the thermometer marked nineteen degrees, with a north-west wind blowing hard. Ice had formed over an inch thick, oranges in the full force of the wind were frozen solid, and on Sunday morning, the 30th, the thermometer marked twenty-eight degrees and afterward rose above the freezing point. In about two weeks the fruit and leaves had nearly all dropped off the trees, and a week later they began to show signs of life. By February 1st shoots had grown from four to six inches, the older leaves were half grown, and many blossoms on the older trees had just opened. The young trees did not fare as well, and in a small three-year-old grove, fully exposed, the trees nearly all had their bark split along the upper part of the trunk, and half of them would have died without any further mishap.

On the 1st of February I was satisfied that I would have three-fourths of a crop, and while the year's income was lost the outlook was not utterly discouraging. Then came the second arctic wave which destroyed the prospects of a crop for years to come. On Thursday, February 7th, 1895, the wind was westerly again and blew as heavily as it did on the 28th of December, but it was not as cold. At dusk the thermometer marked fifty degrees and a meagre weather dispatch

gave no warning that the temperature would fall even to the freezing point. During the night, however, it fell rapidly, and at daybreak marked twenty degrees as before. The temperature all day was near the freezing point, and on Saturday morning it was again nineteen degrees, with ice an inch thick. Saturday it moderated somewhat, and by night the thermometer marked forty degrees, but fell again to ten degrees during the night. This unprecedented fall of thirty degrees in one night was, of course, beyond all former record, and could not have been anticipated without some definite information from the Weather Service Bureau. No one knew how bad we were hurt or what it was best to do, but on Saturday I wrapped the trunks of twenty of my largest trees with burlaps, taking care to protect the bark fully from the sun. On Monday I cut several trees down to the first branch and waited, with such a show of patience as I could command, to see what nature was going to do toward recuperation. It was a terrible ordeal, for the suspense was one of months, for even in the following June we could not tell how much damage had been done, and, in fact, after a lapse of two full seasons I am still uncertain. As a rule, my trees were budded low and on sour stock. In April they began to show signs of life, varying from two to fifteen feet above the ground. Practically all the branches were killed back to the main trunk. Some trees were killed to the ground on the south side, while they threw out vigorous sprouts for two or three feet above the ground on the north. East of the ridge that runs through Rockledge hammock parallel to the river ninety per cent. of my trees threw out sprouts above the bud. Most of the young trees west of the ridge were sawed off even with the ground as soon after the February freeze as possible. Some of the sprouts on the trunk, where the wood did not have vigor enough to sustain life, being a mere shell under the bark, have died during the past years, but not as many as I expected. The crop for the season of 1894-95 was ten oranges. The crop for 1895-96 may be twenty boxes. Owing to the larger portion of roots compared with top there is an excess of sap and food taken up, and the fruit is somewhat coarse. Some of the trees had the red rust, which caused the fruit to split, but this will rapidly disappear as the roots and tops become balanced. The present condition of the trees is satisfactory in the main, and the fruit-bearing wood should give us next year a fair crop, say twenty or more boxes where we now count one. The rapid growth of this new fruit-producing wood will tax our ingenuity to keep it from being crushed by its own weight, as the sprouts have in many instances only a thin shell of live wood to give them strength. These sprouts grow at an angle of forty-five degrees, and when weighted with fruit will need to be supported with the greatest care, or the high winds will break them off, and if exposed to a West Indian cyclone it will be impossible to save them. Buds put in during the summer of 1895 have grown prodigiously, and will soon commence fruiting. The rich, dark appearance of the trees as they glisten in the bright sunshine gives us hope for the future, although much time must elapse under the most favorable conditions before we can fully recover our lost revenues.

In the light of experience I would change my plans but little. If all the trunks of my trees had been well wrapped the morning after the second cold wave, or, better yet, the day before, if the Weather Bureau had given us notice in time, this would have proved of incalculable benefit. I would then cut off the lower branches and the top immediately above the fork. Trees treated in this way are alive on all sides of the trunk, and the branches and sprouts thrown out are more firmly united with the trunk than any others. I would cut down close to the ground every tree less than six years set and draw the dirt away from the collar, so as to expose the surface roots slightly to the sun. As soon as possible I should plow the grove and break as many of the roots as possible, and have a man with a keen grub-hoe following to cut off smoothly the ends of all such roots. I would advise those having small groves to dig a trench ten inches deep, grading the distance from the trunk according to the size of the tree and cutting off all the roots. A few trees treated in this way a year after the cold weather show a marked improvement in growth during the second summer. As soon as the sprouts from the ground are large enough insert the buds or get them started as soon as possible. If this is delayed until the next spring the buds will make too rank a growth. If the ground is in fairly good condition I would apply no fertilizers for two or three years at least. In a young grove where the trees were cut to the ground I would cultivate it and keep it clean, while in older groves, after the first plowing, a circle hoed around the trees will answer every purpose. There is a diversity of opinion as to the number of buds that it is necessary to let grow, and it

will take the experience of years to decide which plan is the best. In my younger trees, where the stump will probably heal over, I have let only one grow, as I much prefer a single trunk. In the case of old trees killed to the ground it will be a temporary makeshift at the best to get a few oranges while the newly set tree is growing, so that it makes but little difference whether two or half a dozen are grown. I am taking advantage of this opportunity to change varieties to the fullest extent, discarding all those that have not proved the best for this locality. I have rebudded all my Navels; have discarded most of the Maltese and imported varieties generally; have reduced the number of Tangerines one-half and added largely to the number of Grape-fruit grafts. I have budded almost exclusively with our best home varieties, adding a limited number of Boones and Parson Browns for early, and Hart's Tardiff and Valencia for late varieties. Nearly every grower has one or more trees in his grove which bear a superior quality of fruit, and from these trees he should take his buds. Indian River oranges have a special quotation in the market, and it is necessary for the reputation of this locality, as well as for individual success, to keep the quality of fruit up to the standard and improve it at every opportunity.

### Conifers on the Grounds of the Kansas Agricultural College.—III.

THE RED CEDAR, EUROPEAN LARCH AND OTHERS.

THE Red Cedar, *Juniperus Virginiana*, has been quite extensively planted, probably next to the Scotch and Austrian Pines in point of numbers, and in general its growth has been very satisfactory. This might have been expected since it is a native of this region. The principal objection to it has been the extent to which it was infested with *Gymnosporangium macropus*. The trees become covered with the brown knots due to this fungus, and after a rain in the spring or early summer are fairly yellow with the gelatinous spore-masses. Before 1895 some desultory attempts were made to pick off these balls, but with no very satisfactory results. In that year, however, a group of Cedars was selected and all of the balls which appeared, even down to the size of a pea, were carefully removed. The result was so encouraging that the practice has been extended to most of the trees on the grounds, with the result that the fungus has been greatly reduced. It is hoped that by continuing this practice systematically for a number of years they may be practically freed from it. Eight Cedar-trees planted in 1872 on the lower part of the farm, where the soil is deep and rich, now average as follows: Height, 31½ feet; diameter at the ground, 13 inches; at 2 feet, 11 inches, and at 6 feet, 9 inches. In 1888 these trees averaged 11½ inches in diameter at the ground, and 8 inches at 6 feet. Thirty-five trees set in groups about the lawns in 1884, and then about 4 feet in height, now average 18¾ feet in height, 8½ inches in diameter at the ground, 6½ inches at 2 feet, and 4¼ inches at 6 feet. Another group of forty-seven trees set in the spring of 1888 at three years old now average 9 feet in height, 3 inches in diameter at the ground, 2¼ inches at 1 foot, and 1¾ inches at 2 feet. The soil is here a clay loam of about ten inches in depth, underlaid by a rather friable red clay subsoil.

The European Larch has not been extensively planted here, but three rows of them stand at the extreme eastern edge of the college premises, where the soil is very deep. They were set in the spring of 1888, and when bought were some sixteen inches in height, but at setting they were cut back nearly to the ground. For the first three years they made comparatively little growth in height, but sent out long side branches, spreading about irregularly over the ground. In the spring of 1892, however, they began to send up strong leaders, and since then they have increased rapidly in height. The three rows above mentioned, some thirty odd trees, now average 16 feet in height, 5½ inches in diameter at the ground, and 3 inches at 6 feet. They seem perfectly hardy and are certainly worthy of more extended trial.

Among other conifers which have been tried in limited numbers, the following deserve mention: The Bald Cypress,

*Taxodium distichum*, is represented by a single old tree set in the spring of 1873, and a number of younger ones set in 1884. They cannot be recommended for general planting, as many of the younger trees have died, and there seems to be a decided tendency for the leader to die, and thus destroy the beauty of the tree, but in some locations they have done well. In 1888 the old tree measured 23 feet in height, 16 inches in diameter at the ground, and 9 inches at 6 feet high. It now measures 24½ feet in height (the leader having died since 1888), 20¼ inches in diameter at the ground, and 12 inches at 6 feet.

The Ginkgo-tree is fairly hardy when grown in sheltered situations, and, although very slow of growth, it is well worth planting where a tree of peculiar habit is desired. A specimen near the college greenhouse, set in 1884, now measures 11 feet in height, 4½ inches in diameter at the ground, and 3 inches at 2 feet.

The Colorado Silver Fir, *Abies concolor*, and the Siberian Fir, *A. Sibirica*, are apparently quite hardy in favorable locations, but so slow of growth as to be valuable only for ornamental planting.

A number of *Arbor Vitæ*s have been tested, but only two are worthy of mention, and these should be planted sparingly and only in favorable, sheltered locations. They are *Thuja occidentalis*, the American *Arbor Vitæ*, and the Siberian, *T. Sibirica*, really a form of the American species.

Agricultural College, Manhattan, Kan.

### Foreign Correspondence.

#### New Garden Plants, 1891-1895.

INSTEAD of reviewing the new plants of the year just ended, I propose to devote this letter to a review of the best of the plants introduced during the five years from 1891 to 1895, inclusive. Plants that promise well when first obtained often turn out failures on further acquaintance, and only a small percentage of the plants that are introduced as likely to prove useful in the garden really do so. This may be due to numerous causes, the three principal of which are want of attractiveness, difficulty of cultivation and slowness of increase. Many Orchids fall under the third category, especially those of hybrid origin. Thus hybrid *Cattleyas* raised twenty years ago are still rare. On the other hand, a few of the quick-growing hybrids, such as *Calanthe Veitchii*, *Cypripedium Leeannum*, *Phajus Cooksoni*, *Disa Veitchii* and *D. Kewensis*, are now so abundant as to be available for all collections.

According to the lists of new plants prepared each year at Kew and published as an appendix to the *Kew Bulletin*, the average number of new introductions is about 400 per annum. For five years this makes a total of 2,000. I have been through the whole of these, and noted all those plants that may now be considered established garden favorites, or on the way to becoming such. These are enumerated below. It is possible that some of those excluded will by some be considered as worthy as some of those enumerated, but, so far as I can judge from experience and observation, the selection here made is not far from the mark.

ORCHIDS.—For obvious reasons hybrids of garden origin are excluded. They are, as a rule, represented by only one or two examples, the exceptions being the hybrid *Disas*. Among tropical Orchids I find only *Cypripedium Charlesworthii*, a first-rate garden Orchid in every sense. *C. Exul* also deserves mention, but I question if *C. Chamberlainii* does. It is a remarkable Orchid, lacking, however, in those qualities required by the ordinary cultivator. *Cochlidoda Noetzeliana* is a good second-rate Orchid for the cool house. *Catasetum splendens*, in all its numerous varieties, is a rich addition to the garden representatives of this singular genus. *Dendrobium Hildebrandii* grows freely and flowers profusely, but its flowers lack the charm of color, and I doubt if it will be accepted as a garden Orchid. *Eulophiella Elizabethæ* is a beautiful Orchid when properly grown, but I hear it is a failure in many collections, and this will

prevent its becoming a favorite. *Habenaria carnea* is distinct and pretty in color, and is easily grown. *Lælia tenebrosa* is the pick of the introductions among Cattleoid Orchids, and *L. Lucasiana* also deserves mention, although it has not proved a free bloomer so far. *Oncidium dichrochum* improves on acquaintance, but it belied its description when first it flowered. *Renanthera Imschootiana* is a beautiful Orchid, and if only it prove a free flowerer it will become one of the most popular of the East Indian introductions.

**STOVE PLANTS.**—There are about a score of these to be added to what we possessed previous to 1891. They are *Aristolochia Gigas Sturtevantii*, *Allamanda Williamsii*, *Begonia decora*, *B. Rex* × *Socotrana*, *B. Gloire de Lorraine*, *B. President Carnot* and *B. Rajah*. These are all really excellent plants which I have seen in superb condition recently. *Bougainvillea glabra Sanderiana* is the freest-flowering of all Bougainvilleas. *Dracæna Godseffiana* and *Sanderiana* are valuable additions to ornamental-leaved stove plants. *Dermatobotrys Saundersæ* is a pretty winter-flowering pot shrub which is certain to find many admirers. It has smooth brown stems and numerous clusters of tubular salmon-red flowers, produced while the plants are leafless. It was introduced from east Africa to Kew a few years ago. *Heliconia illustris* and its variety *splendens* are brilliantly colored plants which pay for liberal treatment and a high temperature. *Impatiens auricomma* makes a shrub a yard high and flowers very freely when planted out in a border. *Nepenthes mixta* is the best of the hybrid *Nepenthes* raised by Messrs. Veitch, or, at any rate, it is as good as their grand hybrid *N. Mastersiana*. *Maranta Sanderiana* is a tall handsome plant with richly colored purplish leaves. *Ptychoraphis augusta* and *Thrinax Morrisii* are two of the most distinct and elegant of Palms introduced within the last twenty years.

**COOL-HOUSE PLANTS.**—There are very few additions in this department. The best are the two yellow *Richardias*, *Elliottiana* and *Pentlandii*. *Alberta magna* is still on trial. I saw a beautiful example of it in flower in the Glasgow Botanic Gardens a few weeks ago. It will probably prove most satisfactory when grown as a shrub in the open air in places where it will be hardy. *Crotolaria longirostrata* is a pretty winter-flowering species which is grown in pots at Kew. *Incarvillea Delavayi* is not satisfactory as a pot-plant, but I hear it is beautiful in some gardens in the open air. *Primula imperialis* will always find friends on account of its gigantic proportions and its interesting character. Only three Ferns deserve mention; they are the hybrid *Polypodium Schneiderianum*, *Pteris longifolia Mariesii* and *Alsophila atrovirens*.

**HARDY HERBACEOUS PLANTS.**—There are many of these recorded as new and interesting, but very few of them have found favor. *Calceolaria alba* is a charming perennial of special interest to the breeder. *Chrysanthemum Nipponicum* is a hardy perennial two feet high, but as it flowers at the end of the year it requires to be lifted in the autumn, or it should be grown in pots along with the common *Chrysanthemums* and treated the same. It produces beautiful Marguerite-like flowers three inches across. *Cineraria maritima aurea variegata* is a prettily variegated plant, useful either for bedding or for pot cultivation. *Dianthus callizonus* is a charming little species with large flowers and is a perfect rockery plant. *Hemerocallis aurantiaca major* is the largest and best of the day Lilies. *Iris Sari*, *Lilium chloraster*, *L. leucanthum* and *L. Lowii* and *Kniphofia Nelsoni* are worthy border plants. *Nemesia strumosa* is better when grown in pots in a frame than as an open-air annual. *Marliac's* new hybrid *Nymphæas* are only prevented from becoming as common as our white *Nymphæas* by their slowness of increase and consequent high cost. *Physalis Franchetii* is as easily grown and fruits as freely as *P. Alkekengi*, its fruits being three times as large. *Senecio saggitifolius* will find favor where it can be grown permanently out-of-doors. *Tulipa Billietiana* is a handsome and distinct addition to the Tulips of the Ges-

neriana class. I have omitted *Calochorti* only because the difficulty experienced in their cultivation here has so far proved a barrier to their becoming popular.

**TREES AND SHRUBS.**—Very few good things are recorded among these, but what there are stand out prominently. We have nothing better in the garden than *Spiræa Bumalda* Anthony Waterer, and no more beautiful white-flowered small shrub than the hybrid *Deutzia Lemoinei*. *Betula Maximowiczii*, for which we are indebted to Professor Sargent, who introduced it from Japan, is a distinct and striking addition to the Birches. *Vitis Coignetæ* is now in every good garden.

London.

W. Watson.

## New or Little-known Plants.

### *Pseudotsuga macrocarpa*.

THIS tree is, perhaps, the most characteristic feature of the scanty forests which clothe the western and southern slopes of the mountains which, extending in the arc of a circle from Ventura County, California, to the southern borders of the state and forming nearly a continuous range, are known as the Saint Emilio, the Sierra Pelona, the Sierra Madre, the San Gabriel, the San Bernardino, the San Jacinto and the Cuamaca Mountains. The rainfall on these mountains is small and unequally distributed through the year; and the forests below elevations of five thousand feet are poor and scanty, and are composed of Junipers, *Pinus attenuata*, *Pinus Coulteri*, occasionally descending from the higher altitudes, where it is more at home, *Pinus ponderosa*, *Quercus Wislizeni*, *Quercus chrysolepis* and the large-coned *Pseudotsuga*, which, so far as is now known, is confined to these mountains. It is common here above the banks of streams and on the steep slopes of narrow ravines between three thousand and five thousand feet elevation, and is able occasionally to maintain a foothold on the drier ridges above, although it does not form continuous groves unless aided by the moisture held in depressions in the mountain-sides, which become torrents at certain seasons of the year. In such favorable positions the large-coned *Pseudotsuga* occasionally attains the height of eighty feet, with a stout trunk sometimes three or four feet in diameter, although trees of this size are exceptional, and this species rarely grows to a greater height than forty or fifty feet. It is a distinct tree, with long, somewhat pendulous and remarkably remote branches which form a broad, open, pyramidal head, foliage of a peculiar blue-gray color, and cones six or eight inches in length. The illustration on page 25 of this issue, made from a photograph taken in winter of a part of the outer wall of the Sierra Madre Range, now in the San Gabriel Reservation, shows the habit of this tree and the manner in which it spreads up the sides of ravines. For the opportunity to use this photograph we are indebted to the courtesy of Mr. Abbot Kinney, of Los Angeles, California, who has sent us an interesting collection of views taken in the reservation.

*Pseudotsuga macrocarpa*, discovered in 1858 on the mountains near the San Felipe by Lieutenant Ives's Exploring Expedition, was first described by Dr. Torrey in 1860 in Ives's "Report on the Colorado River in the West" as *Abies Douglasii*, var. *macrocarpa*. It has usually been considered a variety of the Douglas Spruce, but Mr. Lemmon has considered it specifically distinct, and his opinion appears to be well taken. From the Douglas Spruce it differs in its proportionately longer and more remote branches, in its shorter and stouter winter-buds, and in its shorter blue-gray, somewhat twisted and sharply pointed leaves, those of the Douglas Spruce being obtuse. The cones are from six to eight inches long, or fully twice as long as the largest cones of the other species, but the bracts are proportionately shorter. These characters are constant, and I have not been able to find a tree which appears intermediate in character between the two species, which, so far as I know, do not grow together on the same mountain ranges.

*Pseudotsuga taxifolia* does not extend south on the Sierras below the head of King's River, or to within a hundred miles from the territory occupied by *Pseudotsuga macrocarpa*, and it does not cross the Colorado Desert from the east. If the two trees do grow together it is on the mountains of Ventura or Santa Barbara counties, the southern limits of the range of *Pseudotsuga taxifolia* in the California coast ranges being undetermined.

*Pseudotsuga macrocarpa* is, I believe, still unknown in cultivation. It will probably never be valuable for its timber, but in hot, dry countries like southern California or those bordering the Mediterranean it may prove an interesting and attractive inhabitant of ornamental plantations.

C. S. S.

Alphas just as soon as the ground could be worked in the spring, and ten days later I have planted on the same day Alpha, Premium Gem, McLean's Advancer and Champion of England. These would follow each other in ripening, so that by planting three or four more successions of Champion of England a week apart I would have peas from early in June until the mildew ruined them. Unfortunately, Alpha has become so mixed and degenerated that it can be no longer trusted, but experience with Nott's Excelsior shows that it will be fit for the table about as soon. It is a very dwarf grower, being hardly more than a foot high, and it bears abundantly pods which are tightly filled with peas of the best flavor. McLean's Advancer, an old variety, still holds good for second early. Stratagem, Telephone, Heroine and Admiral have become popular varieties, but a well-selected strain of Champions I still find the most trustworthy. The climbing varieties should

Fig. 5.—*Pseudotsuga macrocarpa* on the San Gabriel Forest Reservation.—See page 24.

## Cultural Department.

### Vegetable Notes.

**Peas.**—These are among the most delightful products of the garden, but since they lose their flavor very quickly after having been picked, none of the early offerings from southern fields can compare with those grown at home. The first dish of peas is, therefore, one of the events of the season, and it was only a few years ago when any gardener in this latitude was considered enterprising if he had green peas with his roast lamb on the 4th of July. Varieties have been produced, however, in recent years which will ripen here early in June, and these, too, of the wrinkled kinds, which are alone fit to plant for home use, since the hard, round, bullet peas are altogether inferior in quality, from lack of sugar and other elements. The difference between Sweet corn and ordinary Field corn is not greater than that between the wrinkled peas and the round peas. For many years I have planted a row of

have brush or netted wire before they fall down. Deep planting, rich, moist soil and clean culture are the essentials of success. After the Peas have well started, a good mulching helps them materially.

**Beans.**—Of Bush Beans, those with round pods, whether they are light-colored or green, are usually the most tender and best-flavored. Different varieties of the Black Wax, Kidney Wax, Refugee and Valentine make compact plants without any runners, having full pods that are slow to become stringy. A year ago this journal contained some notes on the cultivation of garden Beans by Professor Tracy, which have proved of great value to me, as they laid down principles which furnish the reasons for cultural practice. Although these plants grow rapidly when well fed and in the proper kind of soil, yet they are quickly discouraged by any untoward happening or any injury, especially to their roots—that is, the plant, owing to its lack of recuperative power, will be killed or, at least, stunted by any such injury to the root as would make a Lettuce plant or Corn plant grow all the faster. Standing water

about the roots is also fatal, so that a well-drained soil is essential. This lack of ability to recover from any such check means that the main crop should not be planted until the danger of a chill is over, although a few hardy sorts like the Black-eyed Wax may be planted rather early. To avoid injuring the plant and its roots, the soil ought to be made very fine by deep spading, with well-rotted manure thoroughly mixed in when necessary. A dressing of bone-dust and ashes before the crop is planted is also desirable, since the Bean plant needs potash and phosphoric acid more than it needs nitrogen. The ground should be cultivated deeply and thoroughly two or three times before the seed is planted, but after the leaves appear nothing should be done except to cut down the weeds by hoeing on the surface without disturbing the roots. The same principles should be observed in cultivating the climbing varieties—that is, deep and thorough fining of the soil before the seed is sown, and then avoidance of tramping or digging about the roots beyond what is absolutely necessary.

**Peppers and Eggplants.**—Another suggestion of Professor Tracy's which has been very useful to me is that we should remember in caring for Eggplants, Peppers and Tomatoes, that they are annuals that have developed in tropical latitudes. In their native home they grow steadily from the time the seed germinates until the fruit ripens, and it this habit is interfered with the plants are sure to resent it. Plants like Peas which have their home in cold latitudes can remain stationary for a long time under discouraging conditions, and as soon as these are removed they will at once start into growth with increased vigor; but this is not true of these tropical plants, and therefore nothing is gained by sowing the seed until there is just time enough for them to reach the proper size for handling and transplanting when the ground has become permanently warm. If they are forced along before this and then held back by cold weather they will spindle into a soft growth and never yield a full crop.

**Tomatoes.**—This vegetable comes from tropical America, and it requires from 150 to 200 warm days to produce its fruit. A temperature of at least seventy degrees, Fahrenheit, is needed during the growing season of the plant, and Professor Tracy tells us that ten degrees higher than this, both in the soil and air, is required for the best maturing of the fruit. In our northern states this high temperature is only reached during August and early September, and the proper temperature for growth does not begin until the first of June, so that the season must be extended artificially by starting young plants under glass. Here the same law holds that has been alluded to in the case of Peppers and Eggplants. Nothing will be gained by sowing the seed so early that the plants become drawn and spindling, for they will suffer a material check when they are set out. In its native habitat for three or four months the plant grows every day and accumulates enough energy to produce its fruit, and then it dies from exhaustion. If we want a crop of tomatoes in late July or the first of August nothing will be gained by sowing the seed before the 10th of April, because if we give the seedlings the proper light and air and heat to keep them growing strongly, they will be large enough to transplant as early as the soil and air outside are warm enough to receive them without giving them any check. If the seed is sown on the first of March the plants would be of full size by the time it was proper to transplant them. If they have grown so slowly that at the end of these ninety days they are only large enough to set out, this means that they have not acquired that momentum of growth which is necessary to produce the best crop. Of course, there are various methods of transplanting which will forestall any wilting or check from this process, but for ordinary cultivation the seedlings may be put into small pots, shifted on as fast as possible, and while they are growing the ground which is to receive them should be well fertilized and made fine by frequent and deep cultivation, so that the plants may be set out in a warm open soil that has already been cultivated thoroughly and deeply. It is much easier and much better, from every point of view, to do this work before the plants are set out.

**Onions.**—Of course, the so-called new culture is the best. Seed can be sown either in the greenhouse or in a hot-bed about the middle of February, and the seedlings should be transplanted into flats and then hardened off in cold frames. Half an ounce of seed will make enough to plant a large area, enough, indeed, for an ordinary sized family. After the ground has been thoroughly worked in the spring the small bulbs should be set in rows eighteen inches apart, and six inches apart in the row. This crop is very troublesome to keep clean when the seed is sown in drills where it is to grow, but when treated in the way recommended the ground can be thoroughly

cleaned before the young bulbs are transplanted and the labor will be materially lessened. Varieties of a mild flavor are desirable. Prizetaker is one of this kind. It is of good shape, and is also valuable for its long-keeping quality.

Montclair, N. J.

J. A. Newlin.

### India Rubber Plants.

**T**HE India Rubber plant, *Ficus elastica*, is the most satisfactory tropical plant in general cultivation, as it can be grown by everybody successfully, or, to put it more exactly, it is very tenacious of life, and in all positions in the dwelling, greenhouse or conservatory it flourishes with little attention. It revels in abundance of water, yet a temporary dryness distresses it little. Sometimes a fall of temperature will cause it to drop its leaves, making the plants rather unsightly. Judging from the number of leggy and bare plants seen in living-rooms, as well as in greenhouses, it does not seem to be generally known that the production of lateral shoots, or new branches, and bushy specimens is the simplest of horticultural operations. Unless an India Rubber plant is bare in places a single-stemmed specimen, up to five or six feet, is usually the most satisfactory. For larger specimens, or when plants are denuded of leaves, branches are most to be desired. To produce these it is usually recommended to pinch out the leading shoot. This will cause branching, but the new growths are not apt to break where they are wanted most, and, besides this, the loss of the leader spoils the plant as a specimen. The simpler practice is to score the main axis where new growths are desired. By making an incision across the stem with a thick-bladed knife through the bark and slightly into the hard wood, a flow of sap will ensue. This will soon be followed by a callous, and from the edge of this a bud will usually be found in a few weeks. This is simply an exemplification of the well-known fact that buds may be formed from any part of a plant body, and we are all familiar with their occurrence, especially on the stems and roots of hardwood plants. They are more apt to occur near callosities, the result of injuries, or near the axis of a leaf, where food is naturally most abundant. It will usually be most satisfactory to score the India Rubber plant above a leaf scar, and a large proportion of the cuts will prove effective. My observation seems to show that the new buds progress the most rapidly on the part of the stem best lighted, and that the growths are made as rapidly under ordinary house culture as in the greenhouse.

Every one is familiar with the usual practice of shortening India Rubber plants by wrapping sphagnum around the stems where roots are desired. By keeping the sphagnum moist, roots are soon emitted, and the upper shoot may be taken off and planted. They are also propagated in the greenhouse by using single leaves with a portion of the stem, plunging them in sand and keeping at a high temperature. It seems strange that a score kept dry will insure a bud, but if wrapped in a moist medium will produce roots. A ready way to shorten these plants in summer is to bank the earth up the stems, and use the new roots formed instead of the old ones. In this era of rubber-tired wheels, India rubber has become commercially of increasing importance, and the demand for the higher grade of the product is especially urgent, as the lower qualities quickly disintegrate after soft vulcanization. I am told by experts that there is no certain test of the commercial gum, though fine dry "upland" Para gum usually produces good results, yet the industry is always subject to uncertainty from our lack of knowledge of the constitution of this substance. I know of one concern which lost a fortune and its reputation for certain finished goods, which it had maintained for a number of years, because they had unwittingly bought gum from some section where the juice had a different structure, rendering it unfit for vulcanization, yet in appearance and working no expert could determine the difference. We progress rather faster in philosophical deductions than plant-knowledge.

Elizabet, N. J.

J. N. Gerard.

### Seasonable Work.

**A**S the days lengthen, signs of growth will be seen among various plants that have been more or less dormant for some months past, and this means that the time for repotting, dividing and propagating is at hand. Caladiums and Alocasias, after their needed winter rest, are about to start, although the foliage of Alocasias does not die off entirely from some of the species, as it does with Caladiums when they rest. To economize space, many growers shake out Caladium-bulbs in the fall and store them in pans or boxes of sand under the stage

in a warm house, and give them water enough to prevent dry rot during winter. But as soon as the eyes show signs of starting, the roots should be brought out into the light and divided with a sharp knife, and the cut surfaces dipped into slaked lime to prevent decay. Water should be given sparingly until some new roots are made, when the young plants should be set in small pots, using a rather sandy, but rich, compost. They require a warm and moist atmosphere, and should be repotted before the plants become at all stunted. *Alocasia Jenningsii* and *A. Marshallii*, species of moderate growth, are deciduous, and thrive under the treatment suitable for *Caladiums*, but some of the stronger *Alocacias*, like *A. Sedenii*, *A. metallica*, *A. Veitchii*, *A. macrorrhiza* and *A. zebrina*, usually retain some of their foliage, and naturally require more water. They also need more drainage in the pots or pans and a very open compost. When starting into growth again both *Caladiums* and *Alocacias* are very likely to throw up flower-stems, and these should at once be removed, as they tend to weaken the foliage.

The seeds of *Gloxinias*, being very fine, should be sown on the surface of the soil, as Fern-spores are. A safe soil is composed of peat, loam and sand in about equal parts, with some chopped sphagnum mixed through it to keep it more open. *Gloxinia*-seeds should be placed in a warm and moist atmosphere, and should be covered with a sheet of paper until they germinate. This prevents the soil from drying out rapidly, and does away with the need of much watering until the seedlings are visible. Care is needed in handling the young plants, but they are worth the attention.

With stronger sunshine Easter Lilies and the various spring-flowering bulbs will make rapid growth, and a few of the latter should be brought into heat at short intervals for a succession of flowers. With the exception of *Lily-of-the-valley*, a good root-growth is essential before these plants have strong fire-heat, otherwise the flower-stems will be weak and small. Aphides will be sure to find the flower-buds of *Lilium longiflorum*, and are best removed by an occasional dipping in weak tobacco water, a more cleanly remedy than dusting with snuff or powdered tobacco. *Cinerarias*, too, are specially subject to this pest and will require close watching now if the foliage is to be saved. These plants will also need plenty of fresh air to prevent a spindly growth, and as the flower-spikes appear some extra feeding with liquid-manure will be of great benefit.

New Holland plants, such as *Ericas*, *Epacris*, *Eriostemons*, *Boronias*, *Darwinias* and a host of others, are not only notably pretty in form and color, but also fragrant and lasting in bloom. Some of them demand a little extra attention during our hot and dry summers, yet they fully repay the trouble, and a strong point in their favor is the fact that little fire-heat is needed to carry them through the winter. It is a misfortune that they are not more generally grown. The repotting of Palms and many foliage plants had better be deferred for a few weeks, as but little growth will be gained, with the Palms in particular, by shifting them before the roots are making a decided move, and in some instances they will receive a positive check. Special care in firing is needed now, for when the temperature ranges high at night Palms are likely to be excited before their time and thus become weakened. For the species in general use a night temperature of sixty to sixty-five degrees is quite sufficient.

### Anthuriums.

FLOWERS of brilliant color and odd shapes, as well as rich foliage in many cases, give these tropical plants a distinction not only for decorative purposes, but for use in the conservatory with other plants. Nearly all the species do best in a temperature of from sixty-five to seventy-five degrees, which should be kept as nearly even as possible. During warm sunny days the plants need shading, since their native habitat is along the banks of streams and in dense swamps which the sun's rays hardly penetrate. Good potting material is leaf-mold, rotted sod, sand and fine charcoal; they also thrive in well-mixed peat and sphagnum, but when this is used the drainage should be carefully looked after, and they should be potted very firmly. This is a good time to propagate. Small varieties should be divided so as to leave a crown to each plant, while the tops can be cut from the taller ones with a few roots attached, and the old plants will break very readily from below. The raising of seedlings is a slow process, some varieties needing to be fertilized by hand and requiring a year for ripening the seed. The seeds should be sown as soon as they ripen in shallow pans on chopped peat and fresh sphagnum, where they will germinate in seven or eight weeks if placed in

a close frame or under a hand-glass with a bottom-heat of about eighty degrees. As soon as they have formed two leaves they should be transplanted into small pots.

Of the varieties one of the most showy is *Anthurium Andreanum*, which bears all the year round large scarlet flowers which retain their beauty for months together. It is one of the very easiest to grow, and although usually planted in pots we have found that it does admirably in beds. A bed of peat and sphagnum twenty-five feet long and four feet wide was a wonderful spectacle four months after it was filled with these plants. Wherever one has room to spare this certainly proves in the end the most successful way to produce flowers, as we have proved by cutting hundreds of them from this bed every year, some of the spathes measuring more than eight inches long. *A. Scherzerianum* does better in pots. Since its roots are not as long, the plants should be set more deeply, so that the new roots will penetrate through the peat and sphagnum. *A. Rothschildianum* bears very profusely bright scarlet spathes mottled with white. *A. Bennettii* is distinguished by its long and sharply tapering spathe. *A. giganteum* is distinguished for the great size of its flowers, and *A. maximum* produces spathes from seven to nine inches long, four inches wide, and of the most intense scarlet. Among the varieties with decorative leaves are *A. crystallinum*, with leaf-veins of crystal white; *A. triumphans*, with long bright green leaves and prominent ribs of a lighter color; *A. Veitchii*, often called the Elephant's Ear, with leaves from two to three feet long and of a metallic hue; *A. Waroquensis*, with large, striking, rich green leaves of a velvety lustre and paler midribs and veins.

Tarrytown, N. Y.

William Magee, Jr.

**Window Plants.**—At this season house-plants in bloom are grateful for an occasional feeding with liquid fertilizer, which gives the leaves a deeper green and increases the number and size of the flowers. Any perfect commercial plant-food can be used in solution, but cow-manure is quite as satisfactory, especially if a little ashes can be mixed with it for extra potash and the ingredients steeped in a barrel of water for several days. This liquid should then be diluted until it has the color of weak tea, for if applied too strong or too freely it is sure to injure the plants. At first the solution should not be given oftener than once a fortnight, but it can be gradually increased in frequency until it is used as often as once a week or once in five days.

### The Best Winter Pears.

To the Editor of GARDEN AND FOREST:

Sir,—We have varieties of pears in abundance which are suitable for use between the middle of July and the middle of December, a period of five months, but it is greatly to be desired that this period should be doubled in length. The really good varieties which are available for use in winter and spring are few. The Anjou, which bears so well and regularly, I cannot keep after New Year's. Winter Nelis, which is richer in flavor, can be kept until February with very careful handling. Josephine de Malines is not as rich in flavor, and with me it has a marked astringency, although its keeping qualities are so good that it will last till late March. Easter Beurre is of first-rate quality, never ripening with me before March and keeping till April, but it has a serious defect of ripening unevenly. When the side of well-grown specimens exposed to the sun on the tree is in its best form for the table, the shaded side is often so hard that it cannot be eaten. Among the recently introduced late-keeping varieties I have made a fair test of Duhamel de Monceau, Colonel Wilder and P. Barry. Duhamel de Monceau is a fair substitute for Winter Nelis, is larger and handsomer, and is not attacked by any of the fungi to which the Nelis is showing an increasing and discouraging susceptibility. It is juicy and melting, rather than sweet, and not quite equal to Winter Nelis in quality, but still very good. It is not so even a bearer. Colonel Wilder is large, handsome, and, although it is a good pear, its quality is inferior to that of Duhamel de Monceau. P. Barry is also large and handsome; in quality equal to the best of the pears, and it is a great keeper. Its season of ripening extends through April. The tree with me, however, is a slow grower and always inclines to overbear. I have grafted it upon different standard stocks, such as Flemish Beauty, Clapp's Favorite and White Doyenne, on the last of which it has made its best growth. Some of your readers will render a real service to those of us who are experimenting in this direction with the later-keeping pears if

they would give an account through the columns of GARDEN AND FOREST of their personal experience.

## Recent Publications.

### The First Account of Some Western Trees.\*—I.

Lewis and Clark, in their expedition across the continent from the mouth of the Missouri River to that of the Columbia on the Pacific coast during the years 1804-1806, were the first white men to cross the Rocky Mountains within the present territory of the United States, and their geographical and natural history observations are therefore of peculiar interest. The value of the journals of these two great explorers, first edited by Nicholas Biddle, is moreover now greatly increased by the learned notes with which Dr. Coues has enriched a new edition of this classical work. Lewis and Clark were the discoverers of many interesting and important trees, and it is solely with reference to the trees mentioned in their journals that we now propose to examine this new edition.

Following their journey we find (i., 63) that when the party had reached a point 690 miles above the mouth of the Missouri, on the 30th of July, 1804, the *Lynn*, among other trees, was noticed. This is referred by Dr. Coues to *Tilia pubescens*, a species, however, confined exclusively to the coast region of the south Atlantic states; and it is evident that the Linden of the Missouri bottoms was *Tilia Americana*, our common northern species. On the 16th of September (i., 119), not far from the confluence of the White River with the Missouri, the party was encamped "in a beautiful plain, with timber thinly scattered for three-quarters of a mile and consisting chiefly of Elm, Cottonwood and some Ash of indifferent quality, and a considerable quantity of a small species of White Oak." This last Dr. Coues refers to *Quercus undulata*, var. *Wrightii*. More probably, however, the Oak seen here was *Quercus macrocarpa*, which extends farther to the north-west than any of our Atlantic species; and this determination seems to be confirmed by the description of the cup of the acorn "which is fringed on the edges and embraces it about one-half." *Quercus undulata* and *Quercus Gambellii*, the two Rocky Mountain White Oaks, which are often confounded in some of their forms, are not known east of the continental divide north of the Platte River in Colorado. On October 2d the party fell in with a Mr. Valle, a French trader, who had visited the Black Hills, which he described to them as covered with great quantities of Pine (i., 150). This is *Pinus ponderosa*, and probably the first authentic allusion in literature to this widely distributed tree, which was not described technically until the appearance of Loudon's *Arboretum* in 1838. Sergeant Gass, in ascending White River on September 15th (i., 117), had seen, however, Pine burrs and sticks of Birch floating down the river. These Pine burrs must, of course, have been the cones of *Pinus ponderosa* from the pineries of north-western Nebraska.

On April 12th of the following year (i., 268), after the winter passed near the Mandan villages, a species of dwarf Cedar which "spreads its limbs along the surface of the earth, which is almost concealed by its closeness and thickness and is sometimes covered by it, was noticed above the mouth of the Little Missouri." Judging by the description of its leaf, which "is more delicate than that of the common Cedar, though the taste and smell are the same," it is, no doubt, rightly referred by Dr. Coues to *Juniperus Sabina*, var. *procumbens*, which ranges westward to the eastern foot-hills of the northern Rocky Mountains.

The Ash-tree seen on April 20th (i., 277), near what is now the eastern borders of Montana, must certainly have been the Green Ash, *Fraxinus Pennsylvanica*, var. *lanceolata*, as doubtfully determined by Dr. Coues; and in the same paragraph there is a reference to Service-

berries, being the first appearance in literature of the western species of *Amelanchier*, described many years afterward by Nuttall as *Amelanchier alnifolia*, unless, as we suspect, the berries, "which my people called poires, and were of a purple hue, somewhat bigger than a pea, and of a luscious taste," found by Alexander Mackenzie in August, 1789, to the north of Slave Lake, were derived from this *Amelanchier* (*Voyages*, 107). Under the entry of Wednesday, July 17th, 1805 (ii., 419), the western *Amelanchier* is shown to differ in some points from that of the United States; "the bushes," we are told, "are small, sometimes not more than two feet high, and rarely exceeding eight inches. They are proportionally small in their stems, growing very thickly, associated in clumps. The fruit is of the same form, but for the most part larger and of a very dark purple."

On the 11th of May (i., 306), being in Montana, the party saw and visited "some high hills on the north side, about three miles from the river, whose tops were covered with a Pitch Pine. This is the first Pine we have seen on the Missouri; it is like that of Virginia (which Dr. Coues calls *Pinus rigida*), except that the leaves are somewhat longer." This new Pine was *Pinus ponderosa*; and on May 21st (i., 318) the country was found "broken and crowned with some Pine and dwarf Cedar; the leaf of the Pine is longer than that of the common Pitch or Red Pine of Virginia; the cone is longer and narrower, the imbrications are wider and thicker, and the whole is frequently covered with rosin," a good description of *Pinus ponderosa*.

On the Teton River (ii., 356) Captain Clark first noticed a "species of Cottonwood with a leaf like that of a Wild Cherry." This, as Dr. Coues points out, is the narrow-leaved Cottonwood of the Rocky Mountain region, *Populus angustifolia*, here first noticed, although it was not technically described until 1823, after its discovery in the southern Rocky Mountains by Long's expedition to Colorado. It was well described, however, by Lewis and Clark (ii., 364) in their entry of June 12th, when they found it mixed with the broad-leaved Cottonwood, which up to this time had formed the principal timber which they had seen on the banks of the Missouri River.

On July 19th, being in the basin of the Dearborn River and ascending the eastern slopes of the Rocky Mountains, the travelers found (ii., 424) that "the Pine-trees had been stripped of their bark about the same season, which our Indian woman says her countrymen do in order to obtain the sap and the soft parts of the wood and bark for food." This Pine-tree is probably *Pinus ponderosa*, as it is the bark of this species which was most generally eaten in time of famine by the Indians of the west. On the same day were seen on the mountains (ii., 425) "little copses of Pine, Cedar and Balsam Fir." The Balsam Fir is rightly referred to *Abies subalpina* or *lasiocarpa* by Dr. Coues. This is the first mention of the alpine Balsam Fir of the interior north-western region of the continent, with a range extending from Alaska to the Cascade Mountains in southern Oregon, Colorado and northern Arizona, unless this species was one of the Balsams noticed by Mackenzie some years earlier in British Columbia.

On August 3d, the party now being on the Jefferson River, a small species of Birch (ii., 457) was noticed among the shrubs bordering the stream, and described as having "a finely indented oval leaf of small size and deep green color; the stem is simple, ascending and branching, and seldom rises higher than the ten or twelve feet." This is the first account of *Betula occidentalis*, although the western Birch was not described technically until 1839. The mountains at this place are described as "high on each side of the valley, but their only covering is a small species of Pitch Pine with a short leaf, growing on the lower and middle regions, while for some distance below the snowy tops there is neither timber nor herbage of any kind." This Pine is considered by Dr. Coues to be *Pinus flexilis*, the Rocky Mountain White Pine, but this species could never have been mistaken for one of the Pitch Pines, and our

\* History of the Expedition under the command of Lewis and Clark. A new edition by Elliott Coues. In 4 vols. Francis P. Harper. New York, 1933.

travelers, who were certainly familiar with the eastern White Pine, would have at once noticed its resemblance to that tree. It is more probable that they saw the Lodge Pole Pine, one of the forms of *Pinus contorta*, which is one of the commonest trees in this region.

Having crossed the continental divide and being on the waters of the Lemhi River, Captain Lewis found bushes of White Maple on the 13th of August (ii., 487), which Dr. Coues rightly refers to *Acer glabrum*, the only Maple of the Rocky Mountains with the exception, of course, of the Box Elder, which was well known to our travelers and which is quite generally distributed through all this region. *Acer glabrum*, which was discovered at this time, was technically described in 1824 by Dr. Torrey among the plants found by James in Colorado.

On the 23d of August Captain Clark reports on the Salmon River (ii., 532) tall Pine-trees suitable for the construction of canoes. This is another reference to *Pinus ponderosa*, which is the common and largest tree of the region. On September 3d (ii., 579), being then on Fish Creek, before reaching the Bitterroot valley and near the present boundary between Montana and Idaho, he reports the country as well supplied with Pine, and in the low ground "a great abundance of Fir-trees and underbrush." There is some doubt about the identity of these Fir-trees, but it is probably the Douglas Fir or Spruce (*Pseudotsuga*), which is not rare in this region. If this surmise is correct, it is the first reference in this work to this tree which later the party found abundant near the mouth of the Columbia River. On the 9th of September the travelers were crossing the Bitterroot Mountains by the Lolo Pass. Here they found the timber (ii., 596) "almost exclusively Pine, chiefly of the long-leaf kind, with some Spruce, and a species of Fir resembling the Scotch Fir." The long-leaved Pine is, of course, *Pinus ponderosa*. The Spruce is probably *Picea Engelmanni*, which would have been seen here then for the first time by white men; and the Fir "resembling the Scotch Fir" is clearly the Lodge Pole Pine. It may have been this tree which is spoken of as Spruce Pine in the entry of September 12th (ii., 593). Under the entry of September 16th (ii., 598), the party still being engaged in crossing the Bitterroot Mountains, the road was obstructed by "a growth of eight different species of Pine." These must have been *Pinus ponderosa*, *Pinus contorta*, *Abies grandis*, *Abies lasiocarpa*, *Picea Engelmanni*, *Pinus flexilis*, *Pinus Monticola* and *Thuya gigantea*, the evergreen trees which compose the forest of these mountains. Under the entry of September 20th reference is made to an Alder (ii., 605), referred doubtfully by Dr. Coues to *Alnus incana*. It is more probably the *Alnus tenuifolia* of Nuttall, who found it in the Blue Mountains of Oregon and described it in 1842 in the first volume of his *Sylva of North America*. This is the commonest Alder of the Bitterroot region. The Arbor Vitæ reported on this day (ii., 605) as very common and growing to a great size, being from two to six feet in diameter, is referred doubtfully by Dr. Coues to *Thuya occidentalis*. It is really the western *Thuya gigantea*, which ranges from the coast inland to the Bitterroot Mountains and the western slopes of the continental divide in northern Montana, and which, although it had been seen on the coast of British Columbia by Mackenzie in 1793, and by Menzies in 1796, was not described until 1834 by Nuttall.

The Hackberry seen on the 12th of October on the Columbia River (ii., 629), and referred by Dr. Coues to *Celtis reticulata* of Torrey, was more probably the thick-leaved form of *Celtis occidentalis*, which is not rare in the north-west, *Celtis reticulata* being a tree of the south-west, and now usually considered a geographical form of *Celtis Mississippiensis*. On the Columbia they observed the fruit of the White Oak, *Quercus Garryana* (ii., 654), used as food by the Indians, who told them they had procured it from a tribe living near the great falls of the Columbia, where this tree is still common, and where our travelers saw it on the 29th of October growing on hills near the mouth of the Klikat River, in company with a Pine, which is still *Pinus*

*ponderosa*. Near the mouth of Wind River, Oregon, which is just above the town of Sprague, and which Lewis and Clark called "New Timber River, from a species of Ash which grows on its bank, . . . and a timber resembling the Beech in bark, but different in its leaf, which is smaller" (ii., 679). The Ash is *Fraxinus Oregona*, which grows to a large size on the lower Columbia River. The new timber Dr. Coues unhesitatingly called the Broad-leaved Maple, *Acer macrophyllum*, but the large and deeply lobed leaves of that tree could never have been mistaken for the leaves of the Beech. The bark of *Alnus rhombifolia* has some resemblance to that of the Beech-tree, and the leaves are not very unlike Beech leaves in outline. There is certainly no other tree on the Columbia with Beech-like leaves.

The Spruce Pine seen on November 2d (ii., 688) near the Columbia below tide-water, growing with Pine, Cottonwood, a species of Ash and some Alder, was probably *Pseudotsuga*, and the Cottonwood is *Populus trichocarpa*, which is the species of the lower Columbia, and which our travelers had not noticed before. The Pine seen here in low ground is probably *Pinus contorta*. The Ash is *Fraxinus Oregona*, the only species of the region, and the Alder, either *Alnus Oregona* or *Alnus rhombifolia*.

On the lower Columbia, in the entry of November 4th (ii., 693), the Wild Crab was noticed growing near the river. This is the first mention made by Lewis and Clark of *Pyrus rivularis*, which had been discovered a few years earlier by Archibald Menzies. On November 13th (ii., 706), when the party was near the mouth of the Columbia, they found that "the whole lower country was covered with almost impenetrable thickets of small Pine, with which is mixed a species of plant resembling Arrow-wood, twelve or fifteen feet high, with a thorny stem, almost interwoven with each other, and scattered among the Fern and fallen timber." The Pine may have been *Pinus contorta*. Dr. Coues refers the thorny plant to *Crataegus rivularis*. This, however, is a species of the interior; it may have been *Crataegus Douglasii*, or *Pyrus rivularis*, which grows in low ground and is often beset with short lateral, thorn-like branchlets.

On the 18th of November (ii., 712) Pine-trees were seen "three or four feet in thickness growing on the bodies of large trees, which, though fallen and covered with moss, were in part sound." This is a familiar sight in the forests of the north-west coast, where the seeds of several conifers, especially of the Hemlock, *Tsuga Mertensiana*, germinate most readily on the trunks of fallen trees. Having crossed from the north to the south bank of the Columbia on November 26th (ii., 722), they found a "thick growth of Pine, Balsam and other timber." The Balsam here is *Abies grandis*, which the travelers had seen for the first time in descending the western slope of the Bitterroot Mountains. In describing the country in the neighborhood of the winter camp south of the mouth of the Columbia, under entry of November 30th (ii., 724), they say, "the hills along the coast are high and steep; the general covering is a growth of lofty Pines of different species, some of which rise more than two hundred feet, and are ten or twelve feet in diameter near the root." The only trees which attain this size in this region are *Picea Sitchensis*, *Pseudotsuga taxifolia* and *Thuya gigantea*. They noticed here a plant which is called "Laurel," which Dr. Coues considers to be *Rhododendron Californicum* (not *Californianum*), but it is quite possible that by "Laurel" was intended *Arbutus Menziesii*, which is a conspicuous small tree in the coast region at this point.

On the 13th of December (ii., 734) the party were engaged in building huts for their winter quarters, and were rejoiced to find that "the beautiful Balsam Pine splits into excellent boards more than two feet in width." The Balsam Pine is here referred by Dr. Coues to *Pseudotsuga*, but the wood of that tree does not split particularly easily, and the planks were probably obtained from *Abies grandis*, which is abundant here. It is a tree much more readily felled than *Pseudotsuga* and the wood splits easily.

C. S. S.

## Notes.

Under an act of the Legislature the College of Agriculture, at Cornell, offers to give farmers the advantages of the University Extension movement. Any farmer may address Professor Bailey and receive a plan for a course of reading for winter evenings upon topics relating to agriculture, and after reading there can be a discussion with the college. As the spring opens, some simple experiments will be suggested to all readers by which they can test the truth of the principles taught, and there is no expense connected with the work.

An examination for gardeners will be held by the Civil Service Board on January 29th, at the office of the Commission, at ten o'clock, A. M. All persons who desire to try for the position of gardener in the public parks of this city should make application to S. William Briscoe, Secretary of the New York City Civil Service Commission, for blanks, the filling of which will entitle them to examination. Persons who have large experience in general gardening and nursery practice are desired, and every candidate will be required to give letters of recommendation from previous employers.

*The American Florist* reports that from all the important cities during the late holiday season there was a general increase in the sale of plants for holiday gifts as compared with that of cut flowers, and the tendency seems to be more toward the arrangement of plants rather than of cut flowers for the decoration of tables and mantels. This change is attributed partly to the excessive price of flowers which are held in cold storage for holidays and other occasions when there is a large demand for them. Perhaps, however, a sufficient reason will be found in the fact that for many purposes entire plants are a great deal more effective, as they certainly are more enduring.

Mr. George Monro, a fruit dealer in Covent Garden, writes to *The Gardeners' Chronicle* in reference to a statement made in that paper, that the bulk of the fruit sold in England is foreign-grown, to say that while this is quite true as applied to apples and oranges, there never were so few foreign grapes sold in the English markets. Almeria grapes used to be the staple article for Christmas trade, but English growers now furnish a better article in such quantities as to make consumers of the best class quite independent of foreigners. Mr. Monro adds that for four days preceding Christmas he sold four thousand baskets of English grapes, weighing twenty-two tons and a half, and he adds that English growers are now turning the tables on foreigners by sending regularly to America, and almost daily to the Continent, consignments of cucumbers and grapes.

The city of Los Angeles has just come into possession of land which may become one of the most interesting pleasure-grounds in the world. The tract of three thousand acres is situated along the Los Angeles River about a mile north of the city limits, and comprises a rich diversity of soil and surface. It has been known as the Rancho los Feliz, the property of Griffith J. Griffith, Esq., who has presented it to the city of his adoption with the single restriction that if a charter is granted for a railroad to the park from the town a single fare shall be limited to five cents. Part of the land lies within what is called the frostless belt, and it rises over foothills and a mountain slope from whose summits there is a magnificent view, including the city and the sea. Altogether it is a royal gift, and it is to be hoped that the city will appreciate it and see that the natural beauty of the place is not marred by the handiwork of unskilled park makers.

As attractive and toothsome as any of the many table luxuries in the stock of high-class fruiterers and grocers are such choice dried fruits as Malta dates. These come neatly packed in fancy boxes holding a pound of the fruit on one stem, and cost fifty cents. Small boxes of stuffed dates, the kernel of a Pecan nut being substituted for the seed, cost twenty-five cents. Large Smyrna figs, tightly pressed into wooden boxes, cost thirty cents a pound. Carefully selected "pulled figs," known as Royal Locoum, from Turkey, their natural form retained, cost thirty-five cents a pound, and extra-large pulled figs, sixteen of the fruits to a pound box, sell for fifty cents. Square packages, holding four pounds of choice layer figs in attractive silk covers, cost \$1.50. Extra-sized California prunes may be bought for fifteen cents a pound; choice French prunes, esteemed for their rich flavor and more tender skin, cost twenty-five cents a pound in bulk and forty cents in glass jars. Wiesbaden stuffed prunes, the seed space filled with the flesh

of other prunes, are regular articles in trade. Malaga cluster raisins of the high grade known as Five Crown, cost \$1.60 for a five-pound box, or thirty-five cents for a single pound, while the best California raisins cost twenty cents a pound.

General C. A. Andrews, Chief Fire Warden of Minnesota, in an address before the Forestry Association of that state on January 14th, said that during the dry weather in 1895 and 1896, although the seasons were not as dangerous as that of 1894, there were many forest fires, most of which were soon under the control of the fire wardens. He thinks that, owing to the number of new settlers going into the forest regions to open farms, the danger of fires will increase, and the important thing will be to prevent any of them from becoming serious. He argues that it is easy to prevent forest fires in Germany, because every one there is taught in the public schools enough of forestry to give him a knowledge of the value of forests to the country; and inasmuch as forest preservation is best promoted and forest fires most certainly prevented by diffusing a knowledge of forestry and creating an intelligent interest in it, he suggests as a good plan that some of the elementary principles of practical forestry be taught in all the public schools of the state.

In a Farmers' Bulletin on "Irrigation in Humid Climates," by Professor King, it is stated that although the total rainfall in western and southern Europe is materially less than it is in the eastern United States, we must bear in mind that our summer temperature and amount of sunshine are both higher, that the air is less moist, and that under these conditions water is lost from the soil more rapidly by evaporation than it is in Europe, and, no doubt, irrigation might be practiced to as good advantage here as there. In Europe there have been irrigating canals since the invasion of the Moors, and in England there are water meadows so old that no one seems to know their origin. In those places where water is artificially supplied it is thought that the fertility added to the soil is the chief advantage derived from the practice, and for this reason large volumes of water are run over the land during the winter or when it is not occupied by a crop; and, no doubt, it is true that in river water there is much matter of fertilizing power, and that it is more valuable, pound for pound, than solid fertilizers which we buy, because it is already in solution and ready to be taken up immediately. The water meadows of England have been in service without rotation and without the application of fertilizers of any kind for probably five hundred years and they are as productive to-day as ever. These lands are valued very highly because they can be watered for less expense than it would cost to haul manure upon them, even if this could be had for nothing. The crops are absolutely certain, and with from twenty to forty acres of such meadows unirrigated lands can be maintained in a high state of productiveness through the use of the manure made from the product of the meadows.

Among dainty flowers for house decoration displayed in the best shops are branches of white-flowered Almond, the neat little flowers densely set among delicate new leaves. Flowers of the pink variety of the same shrub are also offered, and of the more showy Japan Quince, with masses of Forsythia profusely covered with its yellow bells. Glossy brown shoots of Pussy Willow, dotted with mouse-colored, downy catkins, are shown, and, less freely, apple-twigs in blossom. A well-furnished vase of branches of any one of these forced flowers costs \$5.00. Carnations are now in splendid form; among large, vigorous flowers of many varieties those of the comparatively new Lillie Dean are strikingly handsome; the irregular arrangement of the broad white petals, dashed with red, forms a large bold flower, and the calyx is remarkably good. These sell for \$1.00 a dozen, the price for other varieties ranging from fifty cents to \$1.00. Orchids are lavishly used in some of the window arrangements of first-class floral establishments, but the display is not so extravagant as it appears, since the same flowers which win the admiration of passers-by in the fashionable promenade hours of the day are used in dinner decorations in the evening. Cut flowers of *Cypripedium insigne* and *Dendrobium nobile* cost twenty-five cents each, and of *Cattleya Gigas* twice that amount, and sprays of *Odontoglossum* maximum \$2.00 to \$3.00, according to the number of blooms carried. Flowers of *Amaryllis*, *Lilium Harrisii* and *L. auratum* are offered at \$3.00 a dozen, and *Calla lilies* cost \$1.00 to \$1.50. Among the roses excellent flowers of General Jacqueminot are occasionally seen, but, of course, Bride, Bridesmaid, Meteor and American Beauty are the principal varieties sold, and, like all other flowers, large lots have been selling at remarkably low prices.

## The Need of More Public Pleasure-grounds.

DURING two or three years past several local societies have been formed in England for the purpose of saving from defacement or desecration places which have some special beauty, which command some attractive scenery or which appeal to patriotic feeling by some historical or legendary association. Representatives of these societies now point out that a suitable way of commemorating the fact that Queen Victoria has worn the crown longer than any of her predecessors would be to dedicate pleasure-grounds to the enjoyment of the people forever in various parts of the kingdom. Of course, this scheme is not confined to large towns and cities, but embraces all parts of the country. While localities of historic interest or spots which have some especial charm of landscape are spoken of as preferable selections, the leading purpose is to secure a public pleasure-ground and call it the Queen's Field, or the Queen's Park, or the Queen's Garden, or whatever name would be most appropriate. Hill-tops which command broad views, bits of woodland, stretches of water, still or flowing, cliffs and downs, old castles and other historical remains are all suggested. It is pointed out in the memorial that even in the distinctly rural districts of England there are many counties with no recreation-grounds, no village commons or greens, no playgrounds for children. Instances are given where grounds thrown open to the public, even in remote and solitary places, are no longer solitudes, but are thronged with men, women and children. In speaking of this proposal, *The Outlook* for last week says:

England is rapidly becoming so crowded that even in out-of-the-way places the need of breathing-places for the people is beginning to make itself felt. It would be difficult to imagine a more practicable or charming commemoration of the length of the Queen's reign than that presented by this committee, and it is a suggestion worth careful consideration in this country. No American village ought to be allowed to extend rapidly without retaining some place for a pleasure-ground. Beautiful views in this country are often to be seen only from private property; the places from which they are obtainable are inaccessible by proper paths, and when one reaches them there are no seats or other provision for comfort. In Germany there is always a well-worn path leading to any beautiful view,

and there is generally provision for enjoying the view when one reaches the point. We need in this country a national endeavor to protect our fine scenery and to open it up. We need countless footpaths running from the main roads to points of outlook, and we need provision for rest at these points. All this involves very little expense; it is distinctly educational; and it would go far to ease the pressure of hard conditions on the host of people who now feel that they are cut off from the common enjoyments of life. Beautiful views ought to be public property, for no man owns the landscape, however the fields may be divided among individuals. American communities everywhere could not do better for their citizens and for the future than to cast about for places which, by dedication to public use, may become the pleasure-grounds of the people.

Readers of this journal do not need to be told that we are in full sympathy with these views. It is not mere sentimentalism that has prompted wise men in every generation to put themselves in close contact with the beauty of the outdoor world. It is a recognized truth that communion with nature is an effective agency in establishing a sound mind in a sound body. We, therefore, believe that natural beauty is a possession to be prized and cherished by a community, and we repeat what we have before said, that "the reckless destruction of this beauty is a blow, not only at one of the highest and most satisfactory pleasures of the people, but at the public health and wealth." We believe that it is one of the inalienable rights of man to enjoy natural scenery and the pure delights it offers, and that it is, therefore, one of the duties of society which has inherited this beauty to transmit it unimpaired to posterity. We believe that it should be protected not only against the advertising plague, but against the heedless assaults of business enterprise, for the men who build railroads, sink oil wells and open mines, naturally take no thought of the desolation they make, because no one esteems landscape beauty as one of the vital necessities to the mental and spiritual health of the people. A few forward-looking citizens are protesting against the stripping of the forests from our mountain tops because this impairs the natural and needed supplies of timber and water. Why not protest with the same energy against the destruction of the woods because it mars the beauty of the landscape, which is just as truly an inheritance to be cherished as wood and water? If the moral sense of the people were educated to its proper level the wanton defacement of natural scenery would not only be a misdemeanor in law, but it would be considered an offense against common decency, and the man or corporation who heedlessly and needlessly defaces the beauty of the world would be classed among the enemies of society. It is not only such marvels as Niagara, the Palisades, The Dalles of the St. Croix, the Yosemite Valley and the great gorge of the Colorado which ought to appeal to us as a special charge for which our civilization is responsible, nor is it only places of such notable historic association as Plymouth Rock and Valley Forge and Missionary Ridge which should be held sacred. There is in almost every town some spot invested with a poetic charm, or with some traditional interest which each community ought to feel bound to preserve for its successors.

The scheme for county and township parks like that of Professor McBride, of the State University of Iowa, which we advocated last year, is one that ought to attract attention both in the east and the west. The time may come when wooded parks, if of considerable size, can be made useful as object-lessons in forestry, although this period may be too remote to be seriously considered as an argument for their establishment. In the more recently settled regions of the west such public holdings would be most interesting from the fact that they might preserve the original flora of forest and field before it is laid waste. There is not a town in the east which would not be richer for a few acres of its primeval woods in which were preserved some of the original animals now almost totally exterminated. The bolder features of the land still remain to show something of its primitive form and beauty, but the Hemlock groves which darkened its glens are gone;

its knolls once wooded are bare, and many another picturesque feature which could have been saved fifty years ago is lost forever. There is virgin soil still in the distant west, and it would be a worthy ambition there to save some of these picturesque places and preserve them for public assembly grounds and parks for the people.

The very phrase "pleasure-grounds" gives an unanswerable reason for setting apart such reservations. Of course, people in the country do not need the sight of green fields for the same reasons that people in the city do, but they need refreshment and recreation even more. No life is more monotonous than life on the farm, or in the factory or mine, with its unending round of daily toil. The farmer's family and the farmer himself come into contact with nature, it is true, but it is rather in the way of conflict than of companionship. It is from nature that he wrings a living, and nature is not always kind. Aggressive forms of animal and vegetable life contest his right to win his bread from the soil, and perversities of climate often give aid and comfort to his foes. Life on the farm is often hard enough to make men and women hopeless. There ought to be more holiday time to brighten life; more frequent halts for rest in this sullen march to the grave. Unless more cheer and refreshment is provided—more natural and wholesome recreation—coming generations will bear witness to the depressing power of this pitiless grind in dulled minds and dwarfed bodies. No more delightful change from the hard and narrow lines of rural life can be imagined than that afforded by some alluring pleasure-ground to which country people could be drawn to spend a day now and then in social mood and holiday attire upon the grass and among the trees. A day now and then, with all its hours undarkened by care, with games and music and dancing and neighborly companionship, would have a priceless recuperative value for the rural population of the country.

### Notes of Mexican Travel.—XII.

#### MY SUMMER IN THE VALLEY OF MEXICO.—I.

IT was my happy fortune on my twelfth Mexican journey to settle in convenient quarters in the capital city about the end of May, 1896, for the purpose of studying and collecting the plants of the surrounding regions, but especially those of the Valley of Mexico. Two trained and faithful assistants were with me, an American of two previous journeys, to dry the plants with judgment and skill, and a Mexican who had served me in Oaxaca, but was now drawn from the police force of the city, to accompany me in the field, to make way for me among his countrymen and gather plants with judgment and untiring industry. At first I contemplated trips to certain districts in contiguous states to which I had long been attracted; but, as the season advanced and the richness of the flora near at hand manifested itself, I gave up thoughts of making such digressions, and during all the season scarcely got fifty miles away from Mexico City. It was the Cuernavaca region alone, that region which had so charmed me the previous autumn and had then repaid my exploration with so many novelties, that could allure me away from the wonderful Valley of Anahuac, the fair prize for which Toltec and Aztec and Spaniard and Mexican have successively contended.

Hence it is only of the country lying between Tula on the north and Cuernavaca on the south, a tract lying on the crest of the continent at an elevation of from 7,000 to 10,000 feet, with snow-capped peaks towering on either hand, that I have now to write. In working this region I was in the favorite field of many a botanist from the Old World, many a veteran collector from the time of the courtly Spaniard, Hernandez, down to the days of Bourgeau, who, from gathering the flora of various lands, came finally as botanist to the French Scientific Commission under the rule of Maximilian. Here, high under the bright tropic sun, in an atmosphere always fresh and invigorating, I went forth to

my work in the fields each morning with gladness; and whatever the direction of my search I never failed to bring in at night a burden of choice plants. For this work I enjoyed large advantages over the earlier collectors. Whereas, they at best could only reach the better collecting grounds by long rides in the saddle, and must have worked in much personal peril, I, thanks to the efficiency of the present Government, could feel nearly as secure in remotest cañons as in my native fields; and in modern steam cars could gain the vicinity of nearly all points of botanical interest. The officials of the Mexican Central and the Cuernavaca railroads not only extended to me the fullest courtesies of their lines, but manifested an intelligent and friendly interest in my explorations.

My location was near the station of these two railroads in the Buena Vista quarter of the city. This is the West End of Mexico, the modern and growing part of the city, with open squares and broad clean streets and boulevards, adorned with monuments and statues, sometimes bordered with trees, full of white sunshine and flanked with elegant mansions. All of this is in widest contrast with the East End of the city, the ancient Mexico of the Viceroy, crowded, dingy and dirty. A mile away in the Zocolo, or central plaza, I could take cars of the District and the Valley railroads, the former leading due south ten miles over wet meadows to Talpam, planted at the foot of the hills and close to the east edge of the lava-beds; the latter bearing into the south-west, first over soft meadows, then over dry land and through the suburban villages of Tacubaya, Mexcoac and San Angel to Tizapan, which is situated on the west edge of the lava-beds toward the base of the Peak of Ajusco. Near the northern edge of the lava-beds, between San Angel and Talpam, are the villages of Coyocan and Churubusco. The shady lanes and hedgerows and waste grounds about all these villages of the valley yield not a few plants welcome to the collector. An hour's walk beyond Tizapan brings one to the foot of the factory-town of Contreras by the mouth of a deep cañon which divides the Sierra de Ajusco on the south side of the valley from the Sierra de las Cruces on the west side. But Contreras is best reached by train of the Cuernavaca Railroad; and its environs of flowery hillside and mountain top, of rocky barranca and wet and shady cañon, of mesa and lava-beds offer to the naturalist or the pleasure-seeker, perhaps, the choicest and most varied field of the valley. Scarcely more than a mile beyond Contreras, and close by the station of Esclava, at the foot of Ajusco, are beautiful groves of Pine, *Pinus leiophylla*, with gentle glades dividing them; and behind these you can follow up a mountain cañon into the shade of great Firs, *Abies religiosa*. When the train has carried you along up through woods that are a wild Dahliagarden—masses and masses of flaming blooms, three species of Dahlias in twenty distinct colors—and has brought you up to the heights of the Serrania de Ajusco, you are again in groves of Pine, *Pinus Montezumæ* now, which are equally beautiful, and from which you can look out over the wide panorama of the Valley of Mexico.

For gaining the heights of the Sierra de las Cruces on the west of the valley there is in earliest morning the train of the Mexican National Railroad. After two hours mostly spent in threading deep cañons, we alight on the open and grassy Plain of Salazar, some 10,000 feet above sea-level, where the patriot Hidalgo, with his rude hordes, dealt the Spaniards a first surprising blow in the war for independence and then wandered away from his field of victory to find, through treachery, imprisonment and death. Because I had already worked these mountains during several years, I only returned last season to glean a few last things such as *Weldenia candida*, whose lovely white flowers rise on slender tubes from a star-like cluster of leaves.

The train of the Mexican Central Railroad bears one northward in the morning over flats often planted with Corn, over hills interrupting these and down through the Tula valley, some forty miles from the city. Here we may alight in a region to which I gave considerable attention.

The narrow valley is bordered by bluffs and hills of softest calcareous formation, and about these I found certain plants which Coulter and others discovered about Zimapan, a region of similar soil to the northward, but in the same state of Hidalgo. The most conspicuous of these was *Leucophyllum ambiguum*, a shrub from four to six feet high, with whitened leaves and numerous bluish purple flowers. From Hemsley I fail to learn that Tula was formerly visited by more than one or two passing botanists.

But it was chiefly the lava-beds, or pedrigal (place of rocks), so often mentioned in Hemsley's work, which held me closely about Mexico City till the end of the season. From numerous craters, lofty or low, scattered about the Serrania de Ajusco, that mountain expanse, twenty miles broad and 9,000 to 10,000 feet elevation, bounding the Valley of Mexico on the south, streams of lava have flowed down through a distance of twenty-five miles over nearly all the mountain-side and over the southern edge of the valley, whose altitude is about 7,300 feet. These lava-beds present wide areas of wildest aspect, which are most difficult to travel. Sharp ridges alternate with deep crevasses, while pits and grottoes abound. These tracts are reputed to have been the retreat in former times of dangerous men, of wild cattle and of venomous reptiles. It is probably due to such difficulties and perils that the pedrigal, though coming down so near to the city, appears to have been little explored by the earlier botanists beyond the immediate vicinity of Tizapan and Tlalpam, or San Augustin de las Cuevas (caves), as this town was called in Humboldt's day. Doubtless it was once covered with a scanty forest growth, as are its more remote portions to-day. Only about its borders, and especially in the neighborhood of villages, is it yet overrun by goats and other domestic animals. It still lies and must ever remain an untamable wild, a natural preserve, in whose sheltered and inaccessible recesses numberless species of plants perpetuate themselves in security. As I toiled over it day after day, wandering widely, though constantly harassed by vexatious obstacles, I met with frequent surprises. Plants whose acquaintance I had made in remote states came in view—plants of mountain-top, of plain and of valley. Some of these were met with only once or twice. To my last day there I was wont to find in some peculiar nook a species not encountered there before by me. Hence it is impossible for me to feel that I have exhausted the plant treasures which the pedrigal holds. The track of the Mexico, Cuernavaca & Pacific Railroad is laid across the lava-beds on the sides and on the summit of the mountain, and thus to every one are now opened the interest and beauties of this incomparable region. What a vast and unique natural park is this pedrigal, lying close beside a populous city, and how desirable that it be set apart for a public park, be saved from further spoliation by the wood-cutter and be more extensively opened to travel.

Charlotte, Vt.

C. G. Pringle.

### The Winter Solstice at Madeira.

THE island of Madeira is exceedingly rich in its native flora, and from its situation it has climatic advantages which make its fields and gardens remarkable for the variety and quality of their productions, the rapidity with which one crop follows another, and the general abundance of its fruits and flowers and vegetables. Swift steamers now carry the perishable products of the islands to the English markets and bring numbers of English tourists for a brief holiday to the equable climate, which ranges between extremes of seventy-four and sixty-three degrees, Fahrenheit. It is said that improvements in the water-supply and drainage in the city of Funchal have been undertaken which will give it great additional value as a health resort. M. Grabham, a correspondent of the *London Garden*, writes in such an entertaining and instructive way of the winter aspects of the gardens of Madeira that we reproduce the article almost entire:

The autumnal appearance of the gardens of Madeira is

characterized by a revival and burst of vegetation distinctly vernal, and suggesting the existence of conditions which in point of climate are truly spring-like. Thus, immediately on the fall of the first rains, after a long period of dryness, the ground becomes clothed with new growth; Roses start, bud and blossom, fruit-trees (Apples and Peaches) revive and flower, and there is a general return to an appearance which existed in March and April, though less marked in vigor. Something of this is due to the equivocal character of the climate as to spring and autumn, but much also is due to habit in plant-life and the hesitation shown in adopting the routine of new circumstances; hence, after many years, several species introduced from the southern hemisphere have quietly settled into their original seasons, and have their periods of spring growth and full vigor of flowering at our coldest seasons, even in the mountains—*Acacia dealbata*, for example. Others will maintain as long and completely deciduous a season as they were accustomed to in the north, and decline to be moved by even an excess of sunny, showery summer weather—*Platanus*, for instance. About twelve years ago I introduced a new species of *Pancratium* from South America; these plants have thriven and multiplied, but some groups will spring up, flower and die down in October, and others will perform their functions in March and April. Other and more occult differences exist in the behavior of examples of the same species at varying altitudes, suggestive of profound physiological influences in different environments. But the general effect of the unvarying mildness of the climate of Madeira is to prolong the season of active growth and to render it in many cases enduring and permanent, and in other cases to multiply the periods of growth in number in a given period. The gardens at Christmas are not without a free growth and flower show of most kinds of *Geraniums*, but *Pelargoniums* are generally quite out of bloom now. Familiar annuals are growing rapidly, and some few are in flower—*Stocks*, *Mignonette*, etc. To a new-comer the show of *Roses* is truly surprising, *Lamarque* covering enormous spaces over gateway and balcony with fragrant masses of flowers in countless numbers, while *Adam*, *Cloth of Gold* and other less well-established varieties are among the climbers of the class also in full flower. In the beds almost any kind of *Rose* well known in England is to be seen covered with large attractive blossoms. *Camellias* in all the shades supplied from *Oporto* are in full season in many gardens and in profusion.

Two species of *Bougainvillea* which blossom in winter, *B. spectabilis* and *B. lateritia*, just now cover many a wall and lattice with their deeply colored and prolific flower-bracts. *Bignonia venusta* is quite as striking and extensive. Giant specimens of *Poinsettia* with tree-like growth, great bushes of *Salvia* and *Hibiscus* of several sorts, combine to dazzle and astonish the visitor from the north, while among the usual garden plants are the Sweet Canary Violet, two sorts of *Streptitza*, many kinds and shades of *Azaleas*, splendid *Rhododendrons* (chiefly beyond Funchal), quantities of familiar and unfamiliar *Irises*, all lovely, all quite at home, large bushes of sweet *Olive*, sweet-scented *Heath*, *Lemon-scented Verbena*, showy *Bouvardias* of many shades, long sprays of scarlet *Euphorbia*, hedges of blue *Plumbago* and *Heliotrope*, overhanging bushes of *Brugmansia* covered with white trumpet-flowers, charging the night air with their aroma and reflecting pale light in the bright moon. *Palms* and *Cycads* are intermixed, some in fruit, and specimens of *Aralia*, *Castor-oil Bean* and giant *Echium* are to be seen growing freely with flowering *Aloes*, bushes of *Spiræa*, *Pittosporum* and *Bottle-brush*, which in a Madeira garden live healthily together and confound any preconceived ideas of growth proper to latitude or altitude. Nor do the larger trees offer any more definite idea of a given district or zone, for the deciduous examples of the north and south grow promiscuously and harmoniously with the *Camphor Laurel* from *Formosa*, the *Acacias* of *Australia*, the *Laurels* of *Madeira*, the *Mango* of *India*, with the *Erythrinæ*, *Magnolias*, *Casuarina*, *Bignonias*, *Schinuses*, the *Celtis*, *Cercis*, *Ceratania*, the *Persea gratissima* (with its Pear-like fruit), and every conceivable diversity.

The kitchen-garden is not less interesting or comprehensive, and abounds at this season with green *Peas*, *Beans* and *Lettuce*, with most of the familiar esculents of our home gardens added to the list. Several sorts of *Gourds*, one of them especially (*Sechium edule*), a small and delicately flavored vegetable, almost perennial in habit and yield, a small uncultivated *Tomato*, as well as several important additions to the *Mints* and herbs of our home growth; a *Yam* (so-called) and an important country food, the *Sweet Potato*, a tuberous-rooted *Convolvulus* (one to be seen on every side), and well-known varieties of the *Potato* appear in successive crops. Among

the fruits, Oranges figure conspicuously at this season, and enormous trees are everywhere seen heavily freighted with them. The Tangerines are plentiful and good; the Mango is almost over, and so also the Alligator Pear. Guavas and custard Apples are plentiful; Strawberries are ripening fast, and there is plenty of Apples and Walnuts. Coffee is grown abundantly. Many of us cultivate our own Arrowroot, which is excellent; and much use is made of the so-called Cape Gooseberry (*Physalis Peruviana*). The Citron is only seen in gardens here and there, but grows perfectly, and is most excellently candied in the island, as are also many other fruits in their season.

#### Nectria on Currant Canes.

FOR a number of years there have been complaints from several places in the state of New York of a serious trouble with Currants. Nearly two years ago, from material sent me, it was evident that the trouble was due to the parasitism of a species of *Nectria*. Entire bushes were received, and while the larger part of the canes were dead, most of the roots and some of the lower ends of the canes were still alive. From these living parts of the canes new shoots had developed; in some cases a number of small shoots quite close together, so that the appearance was something like that presented by the so-called witches' brooms. It is not a true broom, however, since the development of the new shoots is not stimulated by the action of the fungus, but is the endeavor of the plant to produce new shoots or replace the dead ones.

The diseased plants first show a yellowing of the leaves. The leaves later wither and fall. The fruit often reddens prematurely, and if the injury is serious some time before the time for ripening the berries often wither. Sometimes the canes are killed before the leaf and flower-buds are fully opened, and in such cases the dried buds with partly opened leaves remain on the canes. Infection probably takes place through some injured or cut surface, and cuttings from diseased plants, or from apparently healthy ones in places where the disease is present, are probably one prolific source of the trouble.

Dr. E. J. Durand, formerly assistant botanist for the Experiment Station, and now instructor in botany in Cornell University, was detailed to study the disease. He visited the districts where the trouble existed, made a careful study of the external symptoms and collected material for a study of the life-history of the parasite. Artificial pure cultures of the fungus were made, and stems containing the conidial stage were placed in a cool, shady place in a small wood in order to obtain a larger number of the perfect stage of the fungus, some of this having been found on the canes from the field at the time the plants were obtained.

Two species of *Nectria* were present, and some careful study was necessary in order to separate the two conidial forms and properly correlate them with the perfect forms. One of the fungi proved to be the well-known *N. cinnabarina*, which is widely distributed both in Europe and America as a saprophyte, but also occurs as a parasite, according to Hartig and others. This *Nectria* was connected with the conidial form known as *Tubercularia vulgaris*. This forms bright pink elevations, which have their origin from the mycelium which grows in the cambium of the cane. These elevated masses of the fungus rupture the bark, and are thus exposed. The spores are borne at the outer surface of this mass, and are thus easily freed and carried to other canes. The perithecia of the perfect form are later borne on this stromatic mass, and are in the form of oval flasks, with a minute opening at the free end. Inside of these flask-shaped fruit bodies are numerous elongated club-shaped sacs, each of which contains eight spores, called ascospores. These ascospores are different in form from the conidia, and are composed of two cells, while the conidia are one-celled.

The other fungus was lighter pink in color than the *Nectria cinnabarina*, and its conidial stage did not appear in the form of a prominent stroma. The perithecia, how-

ever, resemble those of the *N. cinnabarina* rather closely, and care is necessary to discriminate between them without recourse to the microscope. Here, however, we find a ready means of separating the two, for the ascospores of this one are many-celled, the divisions in the spore running both longitudinally and transversely, while the ascospores of *N. cinnabarina* have only one transverse partition. This fungus is the *Pleonectria berlinensis*, Sacc.

The most serious outbreak of the disease occurred in western New York, where a plot of Currant bushes of about three acres was affected. At the time the place was visited, in 1895, the bushes upon two acres had been destroyed and the remainder were badly diseased. A large number of cuttings taken from these plants made very little growth and also exhibited symptoms of the malady. The fact that cuttings showed the disease so soon indicates that plants should not be propagated from diseased stools or even from apparently healthy plants in the vicinage of infected ones. Mayer has shown that this fungus gains an entrance to living plants through wounds or cuttings. Once in the tissue it may become perennial, so that the twigs may contain the fungus at the time of making the cuttings for transplanting. Since the fungus may become perennial in the tissues affected, plants cannot be cured. It would probably be better to destroy them and for a few years plant some other crop in the ground.

The subject is one of such importance that Dr. Durand will prepare a monograph upon it for distribution by the Experiment Station.

Botanical Department, Cornell University.

George F. Atkinson.

#### New or Little-known Plants.

##### *Mespilus grandiflora*.

THIS is a small tree, distinguished by ovate-oblong, crenate and occasionally obscurely lobed dark green leaves pubescent below, foliaceous stipules, large pure white flowers, which are solitary or produced in few-flowered clusters, and lustrous, erect, russet-brown punctate fruit, slightly flushed with red. It has been an inhabitant of European gardens for at least a century, but its origin is uncertain. At different times it has been considered a European and a North American species; C. A. Meyer believed that it was a native of the Caucasus, and Karl Koch and many other authors saw in it a possible hybrid between the European *Mespilus Germanica* and either *Cratægus stipulacea*, a tropical American species, or the eastern American *Cratægus tomentosa*. We have no views to offer on the origin or parentage of this tree. In habit, however, in the general form and color of the leaves, in the flowers and in the rusty color of the fruit, it bears a close resemblance to *Mespilus Germanica*. The fruit, however, is smaller, distinctly punctately dotted, like the fruit of our *Cratægus punctata*, lustrous and tinged with red, and the opening of the calyx-tube is much narrower. In the Arnold Arboretum, where this tree is well established, it grows more vigorously than *Mespilus Germanica*, and its greater hardness might indicate an origin in some cold country like the Caucasus, or a cross, if the plant is a hybrid, with one of our northern species of *Cratægus*.

But our object in publishing the figure on page 35 of this issue, which is a reproduction of a drawing made by Mr. Faxon in the Arnold Arboretum, is not to discuss the origin and history of this tree, but to call attention to its value in northern shrubberies and plantations, where it grows rapidly and is not attacked by the fungal diseases which in this climate defoliate at midsummer several species of *Cratægus*; the flowers are large and abundant, but the leaves, like those of many of the Old World trees, shrivel, turn brown and fall in the autumn without assuming the bright colors which make most North American and eastern Asiatic trees and shrubs such beautiful objects in the autumn landscape.

### The Watering of Plants.

PROBABLY no operation in gardening is so important as that of watering, and none is more difficult for amateurs. A man may succeed in floriculture without having had experience, but if he fails it will almost surely be on account of his lack of knowledge in this particular. Injudicious watering

should be light for nearly all potted plants. It is preferable to have plants in condition to take water every day when the sun shines, and the evaporation ought to be sufficient to carry off a daily supply. If the soil remains moist for two or three days, except in freshly potted plants, I should consider investigation necessary, and would expect to find the roots in an unhealthy condition.

The use of manure-water for potted plants is an important part in their cultivation. The pot should not be too large, and

Fig. 6.—*Mespilus grandiflora*.—See page 34.

ruins more pot-plants than all other mismanagement. It is difficult to correct injury from mistakes in watering. Plants stand drought better than a deluge, but overwatering is the most common mistake. Potted plants which take a long time to drain are seldom in good health. It occasionally happens that plants which have made luxuriant growth choke up the drainage with roots, and unless this trouble is understood, too little or too much water may then be given. Free circulation of air is essential in the soil, which for this reason

it is always creditable to have good specimens in small pots. Small pots are possible only with healthy root-action. For this reason I always examine the vents in new pots, and sometimes have them enlarged. Some large specimen Chrysanthemums completely choked up the drainage through overfeeding, so that a series of holes had to be drilled around the base of the pot to allow the water to pass freely. If the water stands in the pots, air is excluded, and before many days the whole mass of earth would become sour and the plants die. In shifting on a

batch of young plants which it is intended to grow into specimens, though in the course of the growing season they will pass from four-inch into ten or twelve inch pots, it is better to move them by easy stages, say, not more than two inches at a time. It is essential that the roots successively use up the nutriment in each addition of fresh soil. It is well known that if the plants are at once placed into ten-inch pots the roots would strike directly for the sides of the pots, and do all their feeding there. By successive shifts a solid ball of roots is formed, so that when we come to use manure-water none of it will lie stagnant in the ball, where feeding roots cannot act. This is the essence of feeding pot-plants.

The soil for potted plants should be better supplied with plant-food than common garden-soil, as the feeding area is limited. The alkalis in the soil should not be made to supply food faster than it is needed. Water at once makes these available, and too much water means too great a supply, so that freshly potted plants should always be underwatered—just enough being given to keep the roots moving, until they are well established. Rain water is preferable, but the supply is so uncertain that we do not count upon using it. Besides this, our supply would be what is shed by the roofs, and this is often contaminated with lead and oil. We now depend altogether upon the town water. Chemicals as a means of purification render the water hard. It has occurred to me that we should use something to counteract or precipitate these. A little free ammonia would have a softening tendency, and I have found wood ashes to act in the same way. A friend of mine uses a pound of potash to two hundred gallons of water with excellent effect. Of animal fertilizers, the Colorado brand of sheep-manure is one of the best sources of liquid-manure. It is strong, lasting and safe. It is taken from sheds on the ranches, where it is kept dry and undiluted, and with the solid uric salts unleached, and available just as soon as a decoction is made. During the summer season we have a large cask always ready for use. In winter-time one tank is kept indoors especially for it. We place about a peck in a rather open-meshed bag and immerse the whole in about a hundred gallons of water. In this way we get a good clear liquid. Once or twice a week we go over all plants that have exhausted the natural resources of the soil, and pass by the weaker ones. If in good health we have found this treatment acceptable to all kinds of plants, not excepting Orchids and Ferns. *Cypripediums* showed a marked improvement, and *Lycaste Skinneri* never did better than with sheep-manure a component of the soil.

It is sometimes desirable to use chemical manures in liquid form, but they must be applied cautiously. At best they should be used as alternatives to vary the diet. Albert's Horticultural Manure has proved satisfactory with me in the proportion of a pound to a hundred gallons of water. It makes no perceptible difference in the appearance or smell of the water, and is therefore well adapted for use in conservatories attached to residences. It is remarkably quick in its action, but an overdose is disastrous. The good effects from its use are apparent in a day or two. In healthy plants the fresh roots come to the surface in search of it, and the absence of roots is evidence that it is not acting properly. Whenever we have been unfortunate in the overuse of chemical manures we have promptly placed the plants in a tub of clear water to cleanse the soil as soon as possible, and then set them where they could dry out.

### Greenhouse Plants in Flower.

IN a cool greenhouse a large plant of *Imantophyllum cyrtanthiflorum* is blossoming freely now. This plant is ornamental, even when it is not in bloom, on account of its very dark green, vigorous, strap-shaped leaves, which measure about a yard in length. Well-established plants in pots stand a good deal of rough usage and make good companions for such decorative plants as *Aspidistra lurida*, *Lantana Bartonica* and others. The salmon-colored flowers, produced in large umbels above the foliage, last for some time if the plants are kept in a rather cool place. After the plants are well established in the pots they do not need potting annually, and a good top-dressing of rich soil only is required.

One of the best *Acacias* now in bloom is *A. longifolia*, a quick-growing species, with abundant flowers borne on long slender branches. It is useful for cutting, and the flowers last for several days. Another easily grown *Acacia*, flowering profusely now, is *A. armata hybrida*. *Cestrum elegans* helps to brighten up the greenhouse, its long, slender branches terminated with cymes of purplish red flowers.

No greenhouse should be without a few plants of *Boronia megastigma*. Its flowers, although not showy, fill the house with their agreeable odor. Small bushes of *Centradenia floribunda* are always attractive, and the plants are now covered with its *Melastoma*-like flowers. *Centropogon Lucyanus* is an excellent winter-flowering plant, and its showy carmine-colored blossoms are produced for several months. It is not only useful as a decorative plant in the greenhouse, but for cutting, as its clusters of flowers can be procured with a good length of stem. *Strobilanthes amsophyllus* and *S. isophyllus* make nice, compact, bushy plants in one year, and the abundant lavender flowers, while not especially desirable for cutting, make a pleasing contrast with the other plants now in flower.

The deliciously fragrant flowers of *Brunfelsia latifolia* are always pleasing. Upon opening they are of a lavender color, but later become almost white. Although this plant is easy to grow and blossoms freely every season, it is not often seen now.

The long gracetul wreaths of bright orange-scarlet bracts and flowers of *Euphorbia jacquiniæflora* are still in good condition and will be for some time. We could hardly spare this useful plant from our greenhouses. For neat, bushy plants and profuse flowering nothing equals *Libonia floribunda*. Small cuttings struck last year and grown along make beautiful winter-blooming plants now. *Chorizema ilicifolia*, with its deep green Holly-like leaves, is one mass of orange-yellow flowers and will blossom freely for several weeks yet. The old favorite *Peristrophe speciosa* still proves useful. The best yellow-flowered plant now in bloom is *Senecio petasites*. Its large terminal panicles are very showy, and a group of these plants make an imposing mass of yellow. *Tetranema Mexicana* makes a charming dwarf pot-plant not more than six inches high. It is not so imposing as some taller plants, but is useful for edging groups on account of its dense corymb of reddish purple flowers. The pretty little Indian Primrose, *Primula floribunda*, is much admired with its small canary-yellow flowers.

Harvard Botanic Garden, Cambridge, Mass.

### Vegetable Notes.

FROM this time onward for some months every inch of greenhouse shelf-room ought to be occupied, and the forward-looking vegetable grower must be constantly on the alert, or some seed may be forgotten or neglected so long that a neighboring garden will have the earlier crop. It is a matter of professional pride to prevent any such defeat, and if a diary of gardening operations is kept day by day and year by year, and constantly referred to, there is little danger that any seed will be overlooked. Diaries are helpful in many ways, and most interesting for reference, but every skilled practitioner and first-class amateur keeps them religiously. Sowings of a good many vegetable seeds will be required during the next six weeks. To keep abreast of the times it is well to order some of the novelties most highly recommended in the leading catalogues. Our earliest Cauliflower seedlings are now being transplanted into boxes. They will be shifted into four-inch pots later and transferred to a gentle hot-bed about the middle of March. A good strain of forcing Erfurt we find to be the earliest, but we also grow some Snowball to come in later, for when treated liberally in frames they make good heads of a fine flavor. Seed sown now will make good plants well hardened off by the time they can be planted with safety outdoors. A sowing of Early Wakefield Cabbage is also proper now. We generally make our first sowing of Celery about the middle of February, using Golden Self-blanching and White Plume varieties, the first-named being the most reliable here. Sown at this time, well-blanching heads may be had early in August. Celery in the open ground is keeping extremely well this season; Kalamazoo we find the best variety at present, Boston Market being used during February and March.

Early in February we sow a few early Beets, French Horn Carrots and Radishes in sashes, after putting in about a foot of warm manure. Lettuces sown in December are now being planted in a gentle hot-bed. They require care in ventilating and all possible light. No sashes containing fermenting material from which steam rises should be without a chink for air even in the most severe weather, or the plants will surely damp off. In case of snow, if mats and shutters are allowed to lie on the frames for even two or three days at a time, the seedlings will grow weak and spindling. We are likely to have much severe weather still, but there are few days from this time onward when light and a little air may not be given with safety, although, of course, all frames should be closed early,

so that a little sun-heat may be bottled up on cold afternoons. When it is needed a crack of air can be given before nightfall.

Unless a special house is at command, with a strong supply of bottom-heat, Cucumbers will germinate but slowly, yet a good hot-bed starts them quicker than anything else, but sudden falls in temperature are to be expected for some weeks yet, and it is safer to trust to heated glass houses, at least in this section, until toward the end of February. Tomatoes which we commenced to pick fruit from in October are now getting partially spent, and will be shortly thrown out to make room for another crop. We get the best tomatoes in winter by growing them in pots. By confining the roots we secure warmer soil, and we can feed liberally and surely by top-dressings and liquid stimulants. A sowing made in October now has fruit of good size, some of which will be ripe in three weeks' time. Our best indoor variety last season was Eclipse, a Scotch-raised sort, which gave us remarkably fine bunches, some containing twelve to fourteen fruits each. May's Favorite is also a capital variety. We are trying Comet for the first time, which we saw extensively grown last summer in England and Scotland for market. A pinch of seed sown now will give ripe fruit by June, some weeks before any can be gathered outdoors. Aristocrat is likely to be largely grown outdoors the coming season; it proved remarkably prolific last year; the fruits were smooth and even, and did not crack as most outdoor sorts do.

The present is a suitable time to sow a few small pots of Parsley to come in after the present supply in boxes or cold frames has run to seed. Chappell's Matchless and Champion Mess, curled, are capital sorts. Mushrooms are being more generally grown every year, and few places where there are greenhouses or moderately warm cellars need be without them. Our first bed has now been in bearing for two months and shows signs of exhaustion. A dressing of new loam and a watering of warm water will be given in a few days' time and the bed covered with hay, to induce the starting of a second crop. Usually we have turned over our manure very carefully for some time before spawning, to allow the rank heat to escape, but this winter we decided to try a bed made up with hot manure, mixed with an equal quantity of loam, without turning it over at all. The bed heated very quickly, and was spawned at a temperature of one hundred degrees; mushrooms appeared in just one month from the day of spawning, and they are of very splendid quality, just three weeks ahead of the bed prepared in the regulation manner. The question arises, whether it is necessary to go to all the trouble of shaking up and turning over the manure as we have done in the past, when the less troublesome method gives quicker and better returns. We are trying another bed treated in this way, and have recommended one or two friends to do likewise, and if these turn out successfully I shall abandon the old way altogether. A great many Mushroom failures arise from the manure being either too wet or too cold before the spawn is placed in the beds; we have in the past thought it unsafe to spawn until the heat subsided to eighty-five degrees, or thereabout. This season's experience teaches that it is better to do it while the manure is fifteen degrees warmer.

### Trees in Public Parks.

To the Editor of GARDEN AND FOREST:

Sir,—It is with sorrow that I am obliged to confess that I never read your editorial of December 23d, 1896, until January 2d, 1897, but, perhaps, it is even now not too late to express appreciation of your vigorous words respecting the all too prevalent feeling that nothing can justify the felling of a tree. Unless this superstition can be put to rout, we may as well attempt no parks or reservations, for if the axe cannot be kept going, Nature will soon reduce the scenery of such domains to a monotony of closely crowded, spindling tree trunks. Among men versed in such matters there is no question about this. Mr. Olmsted and Mr. J. B. Harrison once compiled a pamphlet entitled *Observations on the Treatment of Public Plantations*, in which they printed about forty quotations from the writings of all the highest authorities, from Loudon to Douglas, and all substantially agree with you in saying that in such places "the axe should never be allowed to rest."

But how shall the use of the axe be guided? This is the practical question for park commissioners, and it seems to me that your editorial gives only half an answer. You recommend the employment of "experts in the care of ornamental trees," and experts must, indeed, be engaged at least as teachers

of technical methods. But how shall the experts themselves be guided? Shall they be permitted to reduce the groves and woods of our public domains to collections of specimen trees, or to the monotony of the typical German forests, as, by the way, they surely will do if they are not controlled? In the landscape of a park your arboriculturist, with his zeal for "good" or "ornamental" trees, is almost as dangerous a person as your horticulturist, with his passion for curious, decorative or novel plants. A good park plan is fundamentally a scheme for the creation of more and more pleasing scenery through modifications to be made in the preëxistent vegetation, by clearings, thinnings, plantings and the like; and only secondarily a scheme for making the resulting scenery agreeably accessible by roads and walks. Engineers who direct the building of park roads are expected to conform their work to the requirements of the adopted general plan. Woodmen, foresters and planters should be similarly controlled by the requirements of the same plan—but you do not say so.

Permit me to add that your incidental remarks about the Boston parks (with which I am familiar) strike me as exaggerated. It is true, indeed, that road construction has proceeded more rapidly than planting and woodmen's work, and that some of the older plantations are suffering for lack of thinning. On the other hand, none of the wooded or planted areas of the Boston parks are yet in the deplorable condition of the border plantations of Brooklyn's Prospect Park, which you mention, nor are they likely to reach that condition yet awhile. The Boston Park Commission, influenced largely by a recent mayor, has simply chosen to spend its money in building roads rather than in tree-cutting, pruning and planting; but it has not been forgotten that woodmen's and planters' work is at least as essential to the realization of the general plans as the work of the engineer, and there is good reason to suppose that this work, the postponement of which has as yet done comparatively little harm, will soon be entered on with vigor.

Brookline, Mass.

Charles Eliot.

[The wise thinning of trees in public parks and other pleasure-grounds demands good judgment, which can come only from knowledge and experience; and in the case of public parks it is a particularly delicate operation because, as our correspondent points out, the requirements of the original scheme of the park must, as far as possible, be preserved. No man should be entrusted with the care of ornamental plantations whose idea of a park wood is a collection of specimen trees, or whose understanding of an ornamental forest does not rise above the utilitarian idea of the greatest product from the smallest area. The man who knows park plantations and their requirements will realize that a park wood is beautiful and long-lived in proportion as its trees are healthy, and that different trees require different amounts of light in order to produce the best sylvan results; and the man who knows his business will produce specimen trees where the plan of the park demands them, and from time to time will thin the trees in woods and groves in such a manner and to such an extent that their sylvan character will be maintained. Men capable of directing such work as this can be trained if there is a demand for their services, and if park commissioners are willing to pay them properly for their technical knowledge; but as long as city officers believe that any man who is strong enough to handle an axe or a saw is sufficiently equipped to plant, prune and cut out park and street trees, there is little inducement for intelligent men to fit themselves to manage municipal plantations.]

Our remarks on the condition of the trees in the Boston public parks are certainly not exaggerated, as any one can see for himself who will examine the plantations in Leverett Park, Jamaica Park or Franklin Park, in each of which natural woods or old plantations stood when the land for these parks was taken by the city. These groves and woods had long been neglected and nothing has been done by the city to improve them during the ten or fifteen years of its ownership, and, as we have already said, they are now in bad condition and need immediate and intelligent care. Many old trees which might have been saved ten years ago are now dead or hopelessly ruined, and neglect and deterioration can be seen everywhere. Our correspondent implies that the money available for park construction in Boston has all been spent in road-

building. Large sums of money have certainly been devoted to the construction of park roads, but the Commission has also spent a great deal of money in erecting ugly, and often useless, park buildings and in expensive masonry construction not always necessary and often of doubtful taste. The Commission, too, has for years maintained a large garden establishment which has been actively and successfully engaged in propagating and planting through the parks herbaceous plants, Honeysuckles, Vincas, Japanese Retinosporas, Golden-leaved Junipers and Elders and many other exotic garden shrubs. It is a question of taste which it is not our purpose to discuss now, whether the masses of weedy garden perennials are properly used along the drives of the Fenway and the borders of its salt marshes, or whether Japanese Retinosporas, Golden Elders and yellow Junipers do not strike false notes in the rural landscape sought for in Franklin Park. Such plants may have been wisely selected for their purpose, but it is certainly not good management, when the amount of money for park-planting is limited, to spend a considerable part of it in this way and leave the parkways unprovided with shade-trees, and allow Oaks, Elms, Chestnuts, Hickories and Beeches which have been growing for more than a hundred years, perhaps, to suffer from overcrowding, insufficient nourishment and the attacks of insects. A Retinospora or a Japanese Honeysuckle may attain its greatest usefulness and beauty in the course of a dozen years, but an Oak or a Hickory will increase in beauty for a century, and may in our climate, if it is properly cared for, last for a century longer. If a choice must be made, our plea is for the Oaks and the Hickories against the Retinosporas, Elders, Honeysuckles and all the garden trash in which park makers seem to delight, and against unnecessary stone and mortar when stone and mortar preclude the proper care of the trees.—Ed.]

#### Pollen-bearing vs. Plant Vigor.

To the Editor of GARDEN AND FOREST:

Sir,—Pollen being generally considered the male element of higher plants is supposed to demand an appreciable portion of the plant's vigor. This hypothesis has gained some credence in the popular mind, and even botanists assume that it is more or less true. Numerous instances of increased vigor and size among emasculated animals are cited to prove that the same principles hold good in the plant world. But this analogy between plants and animals is untenable, since an animal is an individual whose various organs are more or less interdependent, while a plant is a congeries of individuals which are not to the same extent dependent on, but, in a certain sense, at variance with one another. The plant may lose a leaf, a twig, a branch—it may even be destroyed to the root, but life is not necessarily extinct. Under favorable conditions it may spring into renewed activity. The animal, on the contrary, never wholly recovers from the loss of a member, if we leave out of consideration the reproduction of lost parts in some invertebrates, although frequently the other members may acquire an increased development, or enforced inactivity may result in greater size. The loss of one arm in man brings about increased power and dexterity in the other, because of the greater amount and variety of work demanded of it. The loss of reproductive power results in the turning of that energy into other channels, as weight, for example. These principles are supposed to hold in the vegetable world, and on this hypothesis horticulturists base the statement that pistillate strawberries, for example, produce better and more fruit than hermaphrodite varieties, because they do not have the two offices of staminate and pistillate flowers in the same individual.

But, although this theory has gained some currency, there have been no experiments tried, so far as can be learned, to prove it, and it was to test the matter that a series of tests has been conducted by the writer, at Cornell University.

Plants were selected in which the stamens could easily be reached and removed. All were subjected, as far as practicable, to the same conditions of growth—that is, uniform soil, temperature, moisture and light. Plants raised from cuttings were chosen from a large number of one variety, and were as nearly uniform in development as possible. The same care in selection was exercised in the case of seedlings. All shifts

were made simultaneously, and in homogeneous soil. Vegetative conditions, then, being equal, the one factor to be varied was the removal or non-removal of the stamens. One set of plants was allowed to bloom without interference; a second suffered exsection of the stamens in each alternate flower, or, in the case of Geraniums and the like, each alternate truss of bloom was castrated, while all the anthers were removed from the third set. The exsection was performed as soon as fine-pointed tweezers could be inserted into the expanding bud without damage to its perfect development.

At the close of the experiments some of the varieties seemed to have been benefited by the loss of anthers. Most noteworthy of these was *Clarkia pulchella*, in which not only were the emasculated plants more robust and vigorous, but they bore nearly four times as many flowers. On the other hand, some of the plants treated showed little or no effect from the operation. From the experiments thus far made no definite law or laws can be formulated, but from data at hand it seems probable that plants like *Clarkia* and *Geranium*, which have an extended season of bloom, might be aroused to increased effort, while species which have a brief flowering period might show no effect at all, since the plant is practically mature when the flower appears. Further, it is not improbable that plants cultivated for their flowers may show the effect of castration in increased vigor and flower production, while others, like Peppers, might bend their energies toward fruit production. Experiments are still being conducted, and I should be glad to correspond with any one interested in the subject.

Ithaca, N. Y.

Maurice G. Kains.

#### Recent Publications.

##### The First Account of Some Western Trees.\*—II.

On January 8th, 1806, the party ascended a hill above what is now Nehalem Bay (ii., 749) and found "the mountains covered with a very thick growth of timber, chiefly Pine and Fir, some of which, perfectly sound and solid, rise to the height of 210 feet and are from eight to twelve feet in diameter." The Pine and Fir are referred by Dr. Coues to *Abies grandis* and *Pseudotsuga Douglasii*, perhaps correctly, although *Picea Sitchensis* is common here, and the largest tree on the coast. "The White Cedar, or *Arbor Vitæ*," was seen at the same time, and by Dr. Coues was referred to *Thuja occidentalis*. This tree, which was *Thuja gigantea*, is now almost always called Red Cedar on the north-west coast, the term White Cedar, when used at all, being applied to *Cupressus Lawsoniana*, which does not extend as far north as the territory visited by our travelers. The wood of the *Thuja* (ii., 764) was used by the Indians in making their bows. The "light white pine" used by them for arrows, if it was white pine at all, may have been the wood of *Pinus monticola* or of *Pinus Lambertiana*, but as these trees do not grow in this neighborhood, at least in any quantity, it is more probable that this white pine is the wood of *Picea Sitchensis*. The bark of the Cedar (ii., 768) was used in making hats, which were traded with the whites, and this bark, too, interwoven with Bear-grass (whatever that may be), was closely woven into water-tight baskets (ii., 769). It is from the trunks also of this *Arbor Vitæ* that the canoes used by the Indians of the lower Columbia were made (ii., 770), and such canoes were seen by Lewis and Clark fifty feet long, and capable of carrying twenty to thirty persons.

Chapter xxv., at the beginning of the third volume of this edition, is devoted to a general description of the botany and zoölogy, especially of the region of the lower Columbia, and here are well described a number of the peculiar trees of the north-west coast. A shrub (iii., 828), with a "deep purple berry like the huckleberry, terminates bluntly, and has a cap, or cover, at the end. The shrub rises to the height of six or eight feet, and sometimes grows on high lands, but more frequently on low marshy grounds. The shrub is an evergreen about ten inches in circumference; it divides into many irregular branches; seldom more than one stem springs from one root, although the

\* *History of the Expedition under the command of Lewis and Clark*. A new edition by Elliott Coues. In 4 vols. Francis P. Harper. New York, 1893.

shrubs associate very thickly." This plant Dr. Coues refers to *Amelanchier alnifolia*, which he believes becomes semi-evergreen on the Oregon coast. This, however, seems to be a doubtful statement, and wherever we have seen this widely distributed shrub or small tree its leaves are truly deciduous. It was more probably the evergreen *Vaccinium ovatum* than an *Amelanchier* that the travelers tried to describe.

Of the large trees of the coast "the first species grows to an immense size" (iii., 829). "The trunks are very commonly twenty-seven feet in circumference six feet above the earth's surface; they rise to the height of two hundred and thirty feet, one hundred and twenty of that height without a limb. We have often found them thirty-six feet in circumference. One of our party measured one and found it to be forty-two feet in circumference, at a point beyond the reach of an ordinary man. . . . The timber is sound throughout and rives better than any other species; the bark scales off in flakes irregularly round, and of a reddish brown color, particularly the younger growth. . . . The leaf is acerose, one-tenth of an inch in width, three-fourths in length, firm, stiff and acuminate. It is triangular, a little declining, thickly scattered on all sides of the bough, and springs from small triangular pedestals of soft spongy elastic bark at the junction of the boughs." This first species Dr. Coues tells us "is probably *Abies nobilis*, the Red Fir of the Pacific coast." Lewis and Clark, however, probably never ascended the mountains high enough to see *Abies nobilis* or *Abies amabilis* which grow only at considerable altitudes above the sea-level, and their description is an admirable one of the tide-water Spruce, *Picea Sitchensis*, which is the only tree at the mouth of the Columbia which attains the size which they describe. Their second conifer (iii., 830) is correctly referred by Dr. Coues to *Tsuga Mertensiana*. The third species (iii., 831) resembles, they tell us, "in all points the Canadian Balsam Fir. It grows from two and a half to four feet in diameter and rises to the height of eighty or one hundred feet. The leaves are sessile, acerous, one-eighth of an inch in length and one-sixteenth in width, thickly scattered on the twigs, adherent to the three under sides only, gibbous, a little declining, obtusely pointed, soft and flexible. This tree affords, in considerable quantities, a fine, deeply aromatic balsam, resembling the balsam of Canada in taste and appearance. The wood is white and soft." Of this tree Dr. Coues says, "the third species is uncertain, possibly *Thuja gigantea*," but the description points to a Balsam Fir, and evidently to *Abies grandis*, which is the common and only species near the sea-level at the mouth of the Columbia. The fourth species resembles (iii., 831) the second (*Tsuga Mertensiana*) in size. "The bark is of a dark reddish brown, thicker than that of the third species, divided by small longitudinal interstices, not so much magnified as in the second species. In relative position the leaves resemble those of the Balsam Fir, excepting that they are only two-thirds the width and little more than one-half the length, and that the upper disk is not so green and glossy. The wood yields no balsam and but little rosin. The wood is white and tough, though rather porous." This, we suspect, is only a form of the Hemlock, although Dr. Coues believes it to be *Abies grandis*. The absence of balsam would seem, however, to suggest some other genus. The fifth species is probably, as Dr. Coues suggests, the Douglas Spruce, although the thin bark "scaling off in thin rolling flakes" would better apply to *Picea Sitchensis*. The description, however, of the cone of what was believed to be the same tree growing on low marshy ground leaves no doubt of the identity of this last with the Douglas Spruce. The sixth species (ii., 832) "does not differ from what is usually denominated the White Pine in Virginia. The unusual length of the cone seems to constitute the only difference. This is sometimes sixteen or eighteen inches in length and about four in circumference. It grows on the north side of the Columbia, near the ocean." Dr. Coues refers, without hesitation, this tree to *Pinus Lambertiana*, the well-known Sugar Pine. The length of the cone,

if the measurement is correctly given, would certainly point to that tree. No one, however, since the time of Lewis and Clark, so far as we have been able to learn, has ever seen *Pinus Lambertiana* growing north of the Columbia River or north of the Santiam River valley, fully a hundred miles south of the Columbia. *Pinus Monticola*, another White Pine, does grow in the coast region of Washington, but the cones of this tree are rarely more than eight or nine inches in length. The seeds of the Sugar Pine, however, were an important article of food to the Indians of south-western Oregon, and it is not impossible that the cones described by our travelers may have come into possession of some of the Indians on the Columbia River through barter with their southern neighbors, and that Lewis and Clark may have been misled as to the habitat of the trees producing them. At any rate, it hardly seems possible that they could have seen the Sugar Pine.

The seventh and last species (iii., 832), which is described as seldom rising higher than thirty-five feet, with a trunk not more than two and a half to four feet in diameter, is probably a depauperate form of *Picea Sitchensis* to which Dr. Coues has referred it. The tree of the lower Columbia River resembling the Ash, when divested of its foliage (iii., 834), with leaves divided into four deep lobes, is *Acer macrophyllum*, here first described, although a technical description of it was not published until somewhat later. On the same page is the first description, too, of the Vine Maple, *Acer circinatum*. The earliest account of *Sambucus glauca* appears on page 835, where the fruit is well described as pale sky-blue.

In ascending the Columbia on the return journey, on the 4th of April, 1806, the travelers noticed for the first time *Cornus Nuttallii* (ii., 930), and on this day a fallen Fir-tree was seen which, including the stump of about six feet, was 318 feet in length, although its diameter was only three feet. This probably, judging from the small diameter of the trunk in proportion to the height, was *Abies grandis*. Few taller trees have actually been measured in the United States. The Crimson Haw seen on the Walla Walla River on April 30th, 1806 (iii., 979), is probably *Crataegus coccinea*, var. *macracantha*, which would here be near the extreme western limits of its range. The Purple Haw found at the western base of the Bitterroot Mountains (iii., 1041) is referred by Dr. Coues to *Viburnum pauciflorum*. We should have supposed, however, that Purple Haw here means *Crataegus Douglasii*. In the same paragraph there is described "a species of dwarf Pine, ten or twelve feet high, which might be confounded with the young Pine of the long-leaved species, except that the former bears a cone of a globular form, with small scales, and that its leaves are in fascicles of twos, resembling in length and appearance those of the common Pitch Pine." This undoubtedly is another reference to the Lodge Pole Pine, *Pinus contorta*.

On June 15th (iii., 1043), the party, then ascending the upper Clearwater to cross the Bitterroot range, found a "thick growth of Long-leaved Pine, with some Pitch Pine, Larch, White Pine, White Cedar, or Arbor Vitæ, of large size, and a variety of Firs." The Long-leaved Pine here is *Pinus ponderosa*, the Pitch Pine is *Pinus contorta*, the Larch is *Larix occidentalis*, which here first makes its appearance in literature, although it was not described until 1849; the White Pine is *Pinus flexilis*, and the White Cedar, or Arbor Vitæ, again referred by Dr. Coues to *Thuja occidentalis*, is *Thuja gigantea*. The Firs are *Abies grandis* at low elevations, and near the summit of the mountain *Abies lasiocarpa*, these being the only Fir-trees of these forests. The Larch is mentioned again on page 1066 as confined with the Firs to the higher parts of the hills, "while the Long-leaved Pine grows as well in the river-bottoms as on the hills." The Cottonwood mentioned here, "with a wider leaf than that of the upper part of the Missouri, though narrower than that which grows lower down the river," is probably *Populus angustifolia*, a species which varies considerably in the width of the leaves.

On the 25th of July, 1806, Captain Lewis, having recrossed

the continental divide through the low pass which has since borne the names of our explorers, noticed east of the mountains on Maria River (iii., 1097) "three species of Cottonwood, the narrow-leaved, the broad-leaved and the species known to the Columbia, though here seen for the first time on the Missouri." This third species was, no doubt, our eastern *Populus balsamifera*, and not the Pacific coast *Populus tricarpha*, which has not been noticed, we believe, on this side of the Rocky Mountains.

This is the last interesting entry in these journals relating to trees. The two parties into which the expedition had been separated, before it recrossed the continental divide, were now speedily reunited near the mouth of the Yellowstone River, and, rapidly descending the Missouri, were soon surrounded by the familiar trees of the Atlantic forests.

C. S. S.

### Notes.

As in many other garden flowers, great improvements have been made of late years in the *Mimulus*, or Monkey-flower, and now seed of such good strains can be had that it is worth while to sow them even in small gardens where flowers are wanted for cutting. The fine seed should be sown rather evenly in cold frames, and they will give an abundance of rich-colored flowers for a long period from midsummer on.

Mr. John E. Lager, of Summit, New Jersey, who is collecting Orchids in the United States of Colombia, states in the *Florists' Exchange* that the plants are becoming scarce, not only on account of the constant drain upon them for export, but because large tracts of forest are being cut down to make room for Coffee plantations. The belt in which the Coffee-plant thrives ranges from 2,000 to 7,000 feet above the sea-level, and very few garden species of Orchids are found above or below it.

The most beautiful trays and cabinets which come from Japan are made of the dark, irregularly grained and wavy-lined wood of the Keaki-tree, *Zelkova Keaki* once classified by botanists as a *Planera* and closely allied to the Elm. Many of the trays are ornamented with the bark of a species of *Pterocarya*, the eastern representative of our Hickory. This bark is apparently flattened and cut into thin sheets which show attractive concentric markings of dark brown on a lighter ground.

Mr. S. D. Willard, at the meeting of the Ohio State Horticultural Society, spoke of an interesting experiment tried at Geneva last year. An orchard of Greening, Baldwin and Hubbardston Apples was thinned on some of the rows so that an apple was left every four inches, and on others so that there was only an apple for every six inches. On the trees where no thinning whatever was done the apples were small and hardly colored; the apples on the trees thinned to four inches apart were colored well and of fair size, but no buds formed for the next season. On trees thinned to fruit six inches apart the apples were large and so finely colored as to attract the attention of passers on the road several rods away. Besides, this there were well-grown fruit-buds for next year, so that, if nothing prevents, the trees will bear two seasons in succession.

The current issue of the London *Garden* has a colored plate of the old Tea Rose, Madame Charles, as it is grown at Gravetye Manor, and Mr. Robinson, who has tried it in his Rose garden for years, has found nothing more satisfactory or constant than this hardy, patient bloomer with its beautiful buds of exquisite color. This Rose was sent out in 1864, having been raised from seed of Safrano, and it resembles Madame Falcot, which is also from the same parent, but of a feebler growth. The flower is of an apricot color, without the saffron tinge found in Safrano. It is a free grower and has a half-climbing habit, which makes it an excellent variety for the greenhouse in the winter. It is a Rose rarely seen in America, but we remember one plant of it which lived many years on Staten Island with a protection of some burlaps tied about it in the winter, against which coarse manure was piled to the height of some eighteen inches and covering a circle with a radius of two or three feet.

In Farmers' Bulletin No. 45, Mr. F. H. Chittenden, Assistant Entomologist of the Department of Agriculture, gives many interesting facts about the nature and extent of the damage to stored grain caused by insects. Aside from the loss in weight brought about by the ravages of insects, the infested grain is often unfit for human consumption and has been known to cause

serious illness. It is also undesirable for live stock and for seed. Most of our indoor insects are indigenous to the tropics and do not thrive in the cold climate of our northern states, but in the south they have become acclimated, and there they do the greatest damage. It is said that in the state of Texas nearly half the grain is actually destroyed by weevils and rats. The loss to the corn crop in Alabama in 1893 was more than a million and a half dollars. There are seven other states which are subject to the same climatic influences as Alabama, and if we estimate the annual loss at the same percentage we would have a total destruction of nearly twenty millions of dollars in the item of corn alone, while other grains and mill products suffer correspondingly. We have no space to give descriptions of the many weevils, grain moths, flour moths, flour beetles, meal worms and grain beetles which do this injury, or to give anything like a summary of the remedies and preventives advocated. It may be stated in a general way that bisulphide of carbon is the best known remedy against all insects which affect stored products, and for this purpose it is becoming indispensable to the owners of mills and granaries. The vapor of this substance is deadly to all forms of animal life if inhaled in sufficient quantity, and mills and other buildings can be easily fumigated with it.

Besides the large assortments of choice fresh and dried fruits, the displays of preserved fruits in first-class fruit and grocery stores are a surprise in their range and variety. Strawberries, raspberries, red and white cherries, blood peaches and apricots, from Wiesbaden, Germany, are among the handsomest preserves. These rich sweetmeats come in glass, as do many preserved fruits from England and this country. With blackberries, pears, pineapples, quinces and other generally used fruits, there are preserved citron, crab-apples, figs, gooseberries, limes, sweet oranges and tamarinds. A large selection may be made from the less syrupy "canned" fruits in tins, as also in glass, including cranberries, green-gages and many other varieties of plums. Sweet pickled fruits are highly esteemed, and yet more costly are fruits in brandy. These choice specialties are carefully prepared in good brandy by experts selected by the first-class grocers. The brandy is supplied by the firm to insure its uniform quality. Other fruit preparations are jellies, jams and marmalades, and shelves of these smaller packages in plain and fluted tumblers and in white pots include many foreign and native products of really choice quality at remarkably low prices. Cherries in Maraschino, figs in eau-de-vie and in cordial, marrons in brandy and marrons glacés in vanilla syrup, guava syrup and many syrups of domestic fruits, and lime and grape juice give some idea of the variety of treatment in the way of preserving and serving fruits. Extracts for flavoring are another manufactured product of fruits. Bar-le-duc, a French compote of white currants in syrup, is one of the choicest tidbits, and a club-house favorite as a relish with cream cheese. A small glass costs forty cents. The petals of preserved Smyrna roses prove a delicately perfumed and delicious morsel, a small tin costing fifty cents. Canton stem ginger and Kumquat oranges come from China in stone pots, and from India lemon and tamarind syrups, pineapple and mango preserves and marmalades, and guava jelly and guava cheese, besides chowchow of mixed fruits. Among India relishes, mangoes, tamarinds and lemons appear. Pickled products further extend the use of fruits in such delicacies as young walnuts and olives, the latter in great variety of color and form and size.

William Elliott, who nearly forty years ago inaugurated the business of selling plants at auction in this country, and who for a still longer time was one of the leading seedsmen of the country, died on the 16th of January at his home in this city. Mr. Elliott's ancestors for several generations had been gardeners in Scotland, where he was born in 1824. After passing an apprenticeship in the gardens of the Earl of Minto he was employed by Sir John Trevelyan, and Sir William Ingleby, at Ripley Castle, Yorkshire, and afterward in the nurseries about London, and came to this country in 1851. He was employed by Andrew Reid, a Broadway florist, and three years later established the well-known firm of Young & Elliott, on John Street, which is still in existence under the name of William Elliott & Sons. Mr. Elliott was as well known for his kind heart and upright character as for his bluff ways and his ready, though somewhat caustic, wit. He was a man of sturdy constitution, commanding appearance and marked individuality of character. His alertness of mind, his penetrating voice, his fine physical proportions and aggressive manner made him singularly successful in his special business, and for many years he was one of the most prominent figures in the commercial horticulture of this country.

## The Redwoods—a Suggestion.

EVERY one who knows California knows the beauty of the Redwood forest and the value of Redwood lumber, and all Americans should know that the Redwood forest is the richest and most important coniferous forest in the world. It stretches in a maritime belt from the borders of Oregon on the north for several hundred miles southward to the southern confines of Monterey County, California. It is not wide, as the Redwood does not flourish beyond the influences of sea-fogs or ascend to greater altitudes than 3,000 feet. It is unusual, therefore, to find these trees more than thirty miles from the coast; and they grow to the greatest perfection on the banks of streams and the slopes of low cañons facing the sea. Sometimes, especially at the north, the Redwoods form pure forests, their tall shafts standing close together in such dense phalanxes that only Ferns can grow in the perpetual shadow of their spire-like heads; and sometimes they are mingled with Spruces, Firs and Cedars in more open forests which are the favorite home of the Tan Bark Oak. No other forest of conifers is so sublime, and no other forest is so productive. The productiveness of these forests is almost incredible. Fifty thousand feet, board measure, of lumber have been frequently cut from one Redwood trunk, and single acres have produced 1,000,000 feet of lumber, or the yield of some 250 acres of the rich pineries of the south-Atlantic and Gulf states.

Surpassed in bulk of stem only by the Sequoia of the Sierras and in height \* by some of the Australian Eucalypti, the Redwood is without a rival in stately beauty; and the Redwood forest is one of the wonders of the world, and man in his short-sightedness is going to destroy it. Redwood lumber, which is the best building material in the Pacific states, is valuable for innumerable purposes, and the Redwood forests are melting away as fast as human energy, aided by steam and the most perfect machinery, can destroy them. Already this wonder of the world, this great national possession, has passed from the control of the Government into the hands of lumbermen and speculators, and the story of this transaction is not always a

pleasant one. The title to land covered with Redwood trees has sometimes been acquired honestly, but a considerable part of this great timber belt has undoubtedly been stolen from the Government by means of dishonest entries, made possible by the defective and foolish land laws of the United States and the dishonesty of its civil officers; and now it is impossible to find between Smith River and Punta Gorda a single entire section of Redwood forest controlled by the Government. Nor has the Government secured anything like a fair money value for this priceless possession, Redwood land having all been sold at prices varying from \$1.50 to \$2.50 an acre; and the nation's loss from its bad management of this narrow stretch of the public domain alone cannot be less than \$100,000,000. Fortunately, there still remain in the hands of lumbermen vast stores of Redwood timber, and, unless the construction of a ship canal across the Isthmus widens the demand for Redwood lumber in the eastern states and Europe, many years will pass before the Redwood forests are finally destroyed. The Redwood, too, is fortunately possessed of a surprising vitality which enables it to keep up a brave fight against its human enemies. Cut down it springs up again with many vigorous shoots from the stump, and some of these shoots from trees cut near San Francisco forty years ago are already a hundred feet high and promise to grow to a great size. The fires which lumbermen set to clear away the débris of branches and bark before they are able to cut the trunks into lengths suitable for handling, carry desolation in their path, but do not destroy the vitality of the Redwood stumps, which, before a year has passed, are clothed with vigorous shoots. These first operations of the lumberman, reckless and extravagant as they are, do not utterly destroy the forest, which, if it could now be left to itself, would in time recuperate. But the land which bears these great trees will produce crops of grass, and this stretch of the California coast is the best dairy region in the state, so that when the logs have been hauled away to the mill, the ground between the stumps is usually roughly plowed and planted with Grass seed; every Redwood shoot is destroyed as fast as it appears, and at the end of three or four years the reproductive power of the roots is destroyed.

As we have said already, the supply of Redwood lumber is so great that, under existing conditions, it will last for many years, but this forest is the property of individuals who have acquired it for what they can make out of it. Its length of life, therefore, will be dependent on the exigencies of commerce. For purposes of local taxation, land covered with Redwood is valued at something like its market value, and to save the payment of these taxes timber is sacrificed in a ruinous competition which destroys without adequate return. It must be evident, then, that the Redwood forest in its primeval splendor is doomed, and that, sooner or later, the time will come when it will be represented by only a few tattered remnants of its former glory. With it will pass one of the marvels of the world as stupendous in its way as any of the scenic wonders which Americans now count among their great treasures. The wisdom of the nation has set aside for all time a great stretch of the Sequoias of the Sierras that future generations of men may know these trees, but no provision has been made for preserving any part of the Redwood forest for a similar purpose, although one Sequoia forest is as important and interesting as the other, and both are equally wonders of vegetable life. Twenty-five years ago, before lumbermen had learned the value and location of these forests, and the ease with which they could be secured, Congress, without expending a dollar, might have made a great national Redwood park in which all the beauties of this forest might have been preserved forever, but this opportunity is lost. The expenditure at this time, however, of half a million dollars, either by the nation, the state of California or by some rich man or group of rich men anxious to do a great public service, would even now buy enough Redwood-covered land somewhere north of Cape Mende-

\* See page 42 of this issue.

cino to secure a park large enough to preserve the features of this forest. Could this be accomplished—and all that is needed to bring it about is the banding together of a few men and women zealous for this particular cause—the time would come after these great forests have disappeared when such a Redwood park would be one of the most interesting and instructive sights in the world and one of the glories of the United States. To those who have wandered among these mighty trees built up by the slow growth of centuries and felt the inspiration of their solemn beauty, the destruction of the Redwood forests seems to be a sacrilege which never should have been allowed, and, certainly, if some small part of it is not preserved, a great wrong will be done to the world, which will lose, with the passing of the Redwoods, one of its fairest possessions.

### The Height of the Redwood (*Sequoia sempervirens*).

IT has usually been considered by the students of our trees that the Sierra Sequoia was the tallest, as it is the largest, tree in North America. Three individuals, each 325 feet high, have been measured in the Calaberas Grove; and these, so far as I have been able to learn, are the tallest American trees whose heights have been authoritatively recorded. On the 7th of last September, however, General Henry L. Abbot, Mr. John Muir and I were on Eel River, near the lumber-camp at Scotia, California, and measured a Redwood which had lately been felled, and which led us to suppose that this species grows to a much greater height than any other American tree. This particular individual was only 662 years old, with a trunk diameter of ten feet five inches at six feet above the ground, and of nine feet fifteen inches above the ground; it measured 230 feet to the first limb, where the trunk was two feet nine inches in diameter and 340 feet to the top of the stem. In trunk diameter it was smaller than the average size of the trees in this particular forest, which extends without a break for about twenty miles along both banks of the Eel River; its height was not exceptional and may be taken as the average height of the trees in this forest; and the men in this camp who pass their lives in working among these trees were confident that individuals one hundred feet taller than the tree we measured could be found. This, perhaps, is not improbable, as Redwood trunks from fifteen to twenty feet in diameter are not rare, and occasional trees with trunks from twenty-two to twenty-five feet in diameter can be found. Judging by the fact that the Eel River trees, which had grown in a deep alluvial deposit, had only attained a diameter of ten feet five inches in 662 years, some large Redwoods must have lived through several centuries and reached a much greater height.

Of other trees measured in this forest one was forty-three feet in circumference at five feet above the ground; another was forty-five feet in circumference at the same height, and another fifty-two feet five inches. The trunk of another measured four feet three inches in diameter 180 feet above the ground.

C. S. S.

### Notes of Mexican Travel.—XII.

#### MY SUMMER IN THE VALLEY OF MEXICO.—II.

THE Pacific slope of the Serrania de Ajusco is likewise of volcanic character. About six miles east from Cuernavaca, at its foot, a stream of lava two miles wide ran down over the valley. Here, at an elevation of but 5,000 feet, prevail different climatic conditions from those of the Valley of Mexico; hence we find these lava-beds occupied by a sub-tropical forest with trees of considerable size, and in this shelter find shrubs and herbs which are the denizens of warm lowlands. On several trips to Cuernavaca at intervals throughout the summer I could not fail to explore these lava-beds, and I was always repaid by numbers of interesting plants. One of the most showy of these by reason of its clustered stems, three or four feet tall, termi-

nating in racemes of scarlet flowers, a truly striking plant, was a *Lamoureauxia* of recent discovery, L. Nelsoni, Rob. & Greum. The deep-wooded and wet barranca leading from near the town up into the heart of the mountains continued to be an attraction on these visits to Cuernavaca and to yield, as last year, new species, among which I may mention a second species of *Coulterophytum*.

When I arrived in Mexico City at the end of May the hillsides in view in all directions were still brown, and it was not till the middle of July that the tardy rains brought out their verdure, consequently my attention was given during the earlier weeks of the season to such plants as grew about the wet meadows and the canals draining them. Following up my quest of these, we went one day by train of the Inter-oceanic Railroad to Ayotla, about forty miles south-east of the city, and situated, according to the map, on the north shore of Lake Chalco. We found, instead of a lake, only a grassy and reedy savanna, all the better, however, as a field for botanizing. On our way we passed extensive drainage works designed to convey the summer floods of Lake Chalco directly into Lake Texcoco. A few weeks later the opening of the canal was celebrated by a banquet, dignified by the presence of the President of the Republic. When the great drainage tunnel below Lake Texcoco shall be completed, nearly all the lakes of the valley will disappear, and in their places will stretch green pastures and fat fields of tillage. Lake Texcoco offers little of interest to the botanist, and presents no beauty, except when viewed from a distance. Surrounded by alkali flats, which are thinly covered with salt grasses and the few other plants common in such conditions, shrinking low during most of the year within margins of whitened mud, it is the great sink of all the valley.

In strong contrast with all this, however, is Lake Xochimilco, which lies close by the base of the southern hills and is fed by sweet mountain springs. It is separated from Lake Texcoco by the Hill of the Star and a row of volcanoes which are truncated cones, but discharges its waters into that lake by the Viga canal leading through the city. Lake Xochimilco is now but a shallow lake; indeed, as we look over its surface from the Hill of the Star, we see only a green expanse of sedges and reeds, except where its waters are led through artificial ways. On its southern border, hidden under trees except as to the domes and roofs of its few venerable churches, stands the Aztec town from which the lake takes its name. Two routes lead to Xochimilco town, one by boat through the Viga direct from Mexico City, the other by train to Tlalpam, thence on foot or in saddle five miles eastward, at first over an arenal or tract of volcanic sand, which yields its peculiar plants, and finally over a stone causeway lined on both sides by the fastigiated Willows commonly set on the banks of canals throughout the valley. Xochimilco may be called an Aztec Venice. Canals lead in all directions, and bronzed and bare-limbed Indians, the men and boys in white cotton and the women in blue scarfs and scarlet skirts, are deftly propelling their canoes or scows by means of poles and paddles. To this point are brought for shipment to the great city in scows all the products of the mountains to the south, and even from the tropic valleys below Cuernavaca, products of forest, field and village. If it is a market day, we find the town thronged with the Indians from many villages around. The streets and broad plaza are bright with crowds in clean, many-hued attire, and we see much manly beauty to admire, and confess the comeliness of many of these brown Indian maidens and matrons. Their wares in endless variety, products of rude handicraft, with grains, vegetables and fruits, fill the market space and are spread out in the shade of the broad Ash-trees of the plaza.

The lower part of the town is extended over the lake bottom. Here, as for a wide space outside, a network of canals has been dug. With the black humus from these, plats of land, irregular in form and varying in size from a rood to an acre or more, have been built up. These are

held together by the roots of Willows set on their margins, those singularly prim Willows which cast but little shade. As they are of richest soil and are easily watered by splashing or dipping water from the surrounding canals they are kept in constant cultivation and to their fullest capacity. Besides luxuriant crops of corn, garden vegetables of all kinds and choice flowers are grown here for the city markets. On many of the nearer of these plats stand by the water's edge, with canoes drawn up the banks before them, the pretty huts of the owners, the walls of which may be formed of the canes of *Arundo* neatly fastened in line, the thatch formed of its leaves or of marsh grass. Mere basket houses are these, yet they suffice for the simple needs of these happy children of nature. On several visits to these strange scenes we engaged Indians with their boats to convey us through the maze of canals to those more remote in pursuit of water plants or marsh plants. Besides the yellow-flowered *Nymphaea Mexicana*, a white-flowered one was common in still water, presumably *N. tussilagifolia*, Lehm. The flowers of the latter are carefully gathered and appear in great abundance in the flower markets of the city throughout most of the summer. Far more multiplied than these was *Eichornia crassipes*, Knuth, with lovely bluish flowers, of which sheets of blooming plants completely covered the surface of certain coves. The flowers of this plant being too delicate to bear handling like Water-lilies, the entire plant, carefully set in pots or baskets, is carried to town for sale. Along the banks of the canals stood the most stately and showy of Golden-rods, *Solidago paniculata*, DC.

As for the snowy mountains on the south-east rim of the valley, Iztaccihuatl and Popocatepetl, they were not to be included in the field of a single season. I only looked up at them on an autumn day from underneath the sombre giant Cypresses which crown the Holy Hill of Amecameca, scanning with somewhat of awe their vast slopes, cragged and furrowed indescribably.

After the middle of October the rainy season drew to a close. With the drying of the soil and the less interrupted sunshine most plants hastened to maturity and decay. A few, chiefly half shrubs, were making slow preparations for blooming in winter, according to their habit. I could not linger for these, since he who collects in botany must distribute also. So, on the morning of the 8th of November, I was compelled to turn from the valley which had yielded me so much pure delight, from its charm so difficult to define, to travel under skies growing leaden into our drear northern winter.

Charlotte, Vt.

C. G. Pringle.

### *Lilium Humboldtii* and Allied Species.

THE typical *Lilium Humboldtii* has a large ovoid bulb, more or less oblique, and occasionally prolonged laterally in a semi-rhizomatous manner. The scales are thick and the bulb very compact. In height the stem is often above four feet. I have seen it nine feet high, and in one instance a single stalk bore eighty buds. Ten or fifteen flowers in a panicle are common. The lower pedicels are longer, and growing gradually shorter form a broadly conical panicle. The flowers are large and of much substance, of a uniform rich reddish orange spotted with maroon and strongly reflexed. Nature has provided for the weight of the great panicles by giving this Lily a very stout erect stem, which is well furnished with leaves in full whorls.

In its native home in the foot-hills of the main Sierra Nevada, *Lilium Humboldtii* usually follows the belt of Yellow Pine, *Pinus ponderosa*, and grows in the open woods. It does not often grow above the four thousand-foot line, nor on the lower foot-hills. Just how far north it extends I have never been able to learn. I know of it in Tehama County, California, but have never seen nor heard of it in the Mount Shasta region. It has never been reliably reported from any point in the northern Coast Range of California, although I have recently learned of a Lily in Humboldt County which can only be *L. Hum-*

*boldtii* or an unnamed species. Neither have I been able to learn of this Lily in the foot-hills of the lower San Joaquin valley, nor farther south than the Yosemite road. Generally it is strictly a mountain species, but there is one notable exception in the upper Sacramento valley. Some fifteen years ago it grew sparsely at one location in the Oak forest which borders the river. It is now abundant for twelve or fifteen miles along the river. In El Dorado County I saw it flowering to perfection last June. A fire had gone through some second-growth Pines a year or two before, and the magnificent panicles made a gorgeous display high above the Ferns and weeds. The top of the hill had been cleared some years before and was cultivated in grass and grain, but in the new stubble many stubs of the Lily stalks could be seen, and from wounds made by the plow the bulbs had been broken into groups of from two or three to a dozen bulbs. The Lilies are evidently on the increase under the conditions, and the bulbs were very healthy. As a cultural hint I would say that *L. Humboldtii* always grows on well-drained soil. The subsoil is usually rocky, the upper soil clayey or volcanic.

In southern California there are two other strongly marked types of *Lilium Humboldtii*. Of these *L. Humboldtii*, var. *magnificum*, is nearest the northern form. This superb Lily has a large bulb, which is usually broader and rounder than in the type, and which speedily turns purple on exposure to the air. At its best it is even sturdier in growth than the type. The foliage is similar, dark green and glossy; the stem is much darker. The flowers, while of the same form and borne in a similar deltoid panicle, are differently colored. At the middle of the flower the ground-color is a rich orange-red. The maroon spots are surrounded by a reddish circle. On the upper half the reddish circles become larger, until they merge into each other at points, making an irregular combination of dark maroon spots, red ocellations, and of dark reddish orange ground in blotches. This form of *L. Humboldtii* is found in the San Bernardino Mountains which make the southern end of the Sierra Nevada, in the Coast Range, as far north as Santa Barbara, in the Jacinto Mountains, and on some of the islands off the coast of southern California. There are some variations within this range, but I am satisfied that bulbs from all of these localities grown side by side would prove practically identical. From the cultivator's standpoint it is important to observe that while the *L. Humboldtii* of the northern Sierra seldom, if ever, flowers the first year, an ordinary bulb of the variety *magnificum* will bloom well the year it is planted, while even small bulbs of *L. Bloomerianum* almost always do. My information is that the variety *magnificum* usually grows in the deep débris near the streams in shaded mountain cañons.

*Lilium Bloomerianum* is to the variety *magnificum* as a pigmy to a giant. Two or three feet usually measures its slender pale stem, and it is sparsely flowered. The much smaller flowers have a paler orange ground and are not so richly colored. The ocellations and red-blotched apex of segments are the same. The bulbs are small, not averaging one-fourth the size of those of the other forms. I have referred before to the peculiar two or three jointed scales. I have seen bulbs in which nearly all of the upper joints readily rubbed off, leaving a mere stub of a bulb. *L. Bloomerianum* is found in the Pine belt of the high mountains of San Diego County.

The following figures, showing the average size of flowering bulbs of the forms of *Lilium Humboldtii*, may be of interest to some: In 750 bulbs of the typical *L. Humboldtii* 196 were from 9 to 12 inches in circumference, 351 from 8 to 9 inches in circumference, and 203 from 7 to 8 inches. The latter averaged  $3\frac{2}{3}$  ounces in weight; second size,  $4\frac{3}{4}$  ounces, and largest size, 9 ounces, with a few 14 ounces in weight. Bulbs of *L. Humboldtii*, var. *magnificum*, measure about the same, excepting that a few exceed these measurements.

Large bulbs of *Lilium Bloomerianum* will measure 6 inches in circumference and weigh  $2\frac{2}{3}$  ounces. Very

many flowering bulbs measure 3 to 4 inches and weigh 1 ounce each.

*Lilium Columbianum* grows over a wide range of country and in many situations. It is found in Oregon from the coast line and the mouth of the Columbia River, throughout the Coast Range and in the lower portions of the Cascade Mountains. It reaches north-eastern California in Modoc County, and in the state of Washington is found in the southern part in about the same range as in Oregon. I have no accurate information as to how far it extends on Puget Sound, but it follows the Columbia River valley and is found in various portions of north-eastern Oregon, and is close to the Idaho line, to my knowledge. It prefers a sandy, well-drained soil among Ferns in open woods. It is easily grown in cultivation. *L. Columbianum* may be described as a miniature *L. Humboldtii*. The flower has reflexed orange-red segments, finely dotted. The stem is slender, and both it and the leaves are light green. The bulb is compact and ovoid, as in *L. Humboldtii*, but, unlike the latter, the scales are thin. Five hundred average bulbs measure as follows: 100, 4 to  $5\frac{1}{4}$  inches in circumference,  $\frac{3}{4}$  ounce each; 346, 3 to  $3\frac{1}{2}$  inches in circumference,  $\frac{1}{3}$  ounce; 54,  $2\frac{1}{4}$  inches in circumference,  $\frac{1}{5}$  ounce. *L. Columbianum* grows from  $1\frac{1}{2}$  to 4 feet in height, and usually flowers the first year. I find sandy alluvium best answers its needs.

The bulbs of *Lilium Bolanderi* are almost identical with those of *L. Columbianum*. I have not flowered *L. Bolanderi* nor have I seen it in flower. It is described as being from six inches to three feet high and few-flowered. The leaves are whorled and the general habit seems to be similar to that of *L. Columbianum*. The flowers are, however, quite different; the segments are not reflexed, and the flower would seem to be broadly trumpet or bell shaped and nodding. A collector who saw it in full flower this year describes it as a very handsome flower of a pleasing red and growing in a high mountainous region in a soil of rocky debris and leaf-mold. Habitat indefinite, Humboldt and Del Norte counties, in north-western California.

In this group will fall a fourth species of the far north, related to *Lilium Columbianum*, and as yet unnamed. In this species the habit of *L. Columbianum* in bulb and leaf is combined with a peculiar-shaped flower. The lower half of the segments forms a closely constricted tube, from which the upper portion spreads horizontally in a rotate flower finely dotted with maroon. This species is nearly as fragrant as *L. Parryi*.

## New or Little-known Plants.

### *Tillandsia Dugesii*.

A VERY beautiful *Tillandsia* has recently been received at the Gray Herbarium of Harvard University from central Mexico. The plant was collected in the mountains of Santa Rosa, Guanajuato, by Professor Alfredo Dugès, and it proves to be the rare *Tillandsia Dugesii*, described ten years ago by Mr. J. G. Baker.\* Though Mr. Faxon's drawing (see page 45 of this issue) does not reproduce the delicate coloring of the plant it gives a good idea of its habit. The leaves are two feet long or more, densely rosulate, with narrowly ovate bases from four to six inches long and from two to two and a half inches wide, tapering to the elongated rigidly coriaceous ensiform-setaceous upper portion, which is convolute nearly to the tip. The leaves throughout are glaucous, with minute lepidate dots. The peduncle is much shorter than the leaves and is closely sheathed by bracts. The lower bracts are as long as the leaves, and like them are lepidate, but their bases are glossy and crimson. The bracts of the panicle are smaller and shorter, and toward the top of the panicle they become merely ovate with acuminate tips. The panicle is a foot or more long, consisting of from fifteen to thirty spikes, these spikes being about three inches long and

scarcely an inch broad. The rachis is crimson and glossy. The flower bracts are one to one and a half inches long, ovate, acute, and strongly keeled on the back; they are either very sparingly lepidate or quite smooth, and of a peculiar greenish straw-color, shading to rose. The calyx is an inch long, composed of three lanceolate-acute conduplicate sepals with sharp keels. The corolla is about half an inch longer than the calyx, and apparently deep purple, with ovate-lanceolate obtuse blades. The stamens are a little shorter than the corolla. Mr. Baker described this species from a plant with neither corolla nor fruit, and as yet the fruit is unknown. The very long glaucous foliage and the brilliant peduncle and rachis make it a plant worthy a place in the greenhouse, and, though the specimen at hand is somewhat wilted, Mr. Cameron will attempt to grow it in the Botanic Garden.

Gray Herbarium, Cambridge, Mass.

### London Letter.

**CHRYSANTHEMUM NIPPONICUM.**—This is a Japanese plant of considerable promise. It is closely related to the European Ox-eye Daisy, *Chrysanthemum leucanthemum*; indeed, it is catalogued by the Japanese nurserymen as *Leucanthemum Nipponicum*. Although described by Franchet in 1872 from specimens collected in Nippon by Savatier, it does not appear to have attracted the attention of European cultivators until 1895, when Messrs. Dammann & Co., of Naples, sent it out as a new plant. It is a perennial shrub about two feet high, with numerous annual stems not unlike those of the common *Chrysanthemum*, oblong toothed leaves, and numerous erect axillary scapes bearing each a head three inches across, with a large yellow turbinate disk and broad, overlapping, pure white ray florets. A German horticulturist speaks highly of it as a winter-flowering plant for the greenhouse. The cuttings are struck in April, and the plants treated as for the ordinary *Chrysanthemum*, housing them in the autumn to flower in December and January.

**HYBRID CINERARIAS.**—Various crosses between distinct species of *Cineraria* have been made in England recently, and the results obtained are most gratifying. The most recent cross has been obtained by Mr. Lynch, Curator of the Botanic Gardens, Cambridge, who crossed *C. multiflora*, a native of the Canary Islands, figured in *The Botanical Magazine*, t. 4994, as *Doronicum Bourgasi*, with forms of the common *Cineraria*, supposed to be a garden evolution from *C. cruenta*, also a native of the Canary Islands. The first named has tall stems three to four feet high, with large orbicular leaves, the lower petiolate portion bearing lobelike leaflets and large auricular clasping bases; the flowers are of a uniform soft mauve color, about an inch in diameter, and borne in very large sheaf-like clusters. The hybrids are mostly like *C. multiflora* in habit, but shorter, while the flowers are much larger and show variations in color similar to those of the other parent. Mr. Lynch showed his hybrids at the last meeting of the Royal Horticultural Society, where they attracted considerable attention. A remarkable circumstance in relation to these hybrids is that Mr. Lynch did not take any steps to prevent self-fertilization beyond covering the heads intended to be pollinated with muslin, in order to exclude insects. He says no further precaution, judging by results, appears to have been necessary. In no case was any true *C. multiflora* obtained from the seed saved, and therefore it may be assumed that this species is sterile to its own pollen, or, at any rate, pollen from another species was more effective. One of the best of the hybrids, named *C. Lynchii*, is remarkable for its numerous flowers in large loose heads and uniformly colored a most pleasing shade of bright rose-mauve, not the harsh mauve so prevalent in the garden *Cineraria*. It grows to a height of about three feet, and is therefore effective in the same way as *C. cruenta*, the type

\* *Journ. Bot.*, 1887, p. 278.

Fig. 7.—*Tillandsia Dugesii*.—See page 44.

1. Plant, about one-fourth natural size. 2. Upper portion of inflorescence, natural size. 3. A flower, natural size. 4. A petal, natural size.

which at Kew is a most useful decorative plant for the conservatory.

*POLYGONUM BALDSCHUANICUM*.—I drew attention to this plant a few weeks ago when it was an attraction in the herbaceous collection at Kew. Some additional informa-

tion is now published in *The Gardeners' Chronicle*, along with a reproduction of a photograph of a fine specimen of it grown by Monsieur Lemoine, of Nancy, with whom it has grown exceptionally well, planted at the foot of a dead Elm-tree, up which it climbed to a height of ten feet and

covered the lower branches with its twining stems, which bore all the summer multitudes of panicles of white flowers. This was its behavior at Kew, where, however, it was planted to scramble over a sheaf of "pea-rods." It is a hardy perennial with wiry stems, cordate deciduous leaves and *Spiræa*-like panicles of flowers. It is a native of Turkestan at an altitude of from four to five thousand feet, where it was found and introduced by Dr. Regel in 1882. It obtained a first-class certificate from the Société Nationale d'Horticulture de France in September, 1894.

**CYCLAMEN PERSICUM.**—An interesting sport from the Persian Cyclamen was exhibited this week by Monsieur de Langhe, Brussels, under the name of *C. Papilio*. It differed from the usual form in having the segments of the flowers spreading horizontally instead of being perpendicularly reflexed, and in the margins being crisped and undulated. Six named forms were shown and they differed from each other in size, color and degree of crispness. Although quite distinct from any other hitherto known sport they were considered inferior in decorative value to the normal form, of which some remarkably fine examples were shown by Major Joicey, of Ascot. At the preceding meeting of the Royal Horticultural Society, Messrs. H. Low & Co. exhibited a sport with a curious feather-like secondary segment growing crest-like from the middle of the normal segment. This character is reproduced in the majority of the seedlings obtained from seeds saved from these feather-crested forms. It will be interesting to watch the development of these two sports. So far as I know, *C. persicum* has not been crossed with any other species of Cyclamen.

**LATE CHRYSANTHEMUMS.**—The two best that I have seen this season are *W. H. Lincoln* and *Princess Victoria*, the former a Japanese reflexed, very floriferous, the color a brilliant deep yellow, and the flowers lasting a month or more. It forms a very shapely bush when grown on what we call the natural method, and is in every sense a most decorative conservatory plant during December and January. *Princess Victoria* is also Japanese reflexed, the flowers large and full and pure white. It is at its best in January, and unless visited by heavy fog it lasts well. It was shown as a new variety in 1892, when it obtained an award of merit. I recently noted that *Madame Therese Rey*, a white Japanese, is at its best in January. Late-flowering varieties deserve more attention at the hands of breeders than they have yet received. We have numerous varieties which flower soon after midsummer and very useful they are, but good sorts to flower in January and February under ordinary treatment are still a desideratum with flower growers.

### Close Root-pruning for Trees.

THE radical change in the method of transplanting trees from the nursery to the orchard, which has been within a few years past advocated by Mr. Stringfellow, of Texas, has set many tree planters to thinking and experimenting. The counsel to beginners used to be to get all the roots possible when the tree is set out. Mr. Stringfellow claims that this is unnecessary, and that, in fact, the tree will make a better growth if the roots are about all removed, and the top, of course, removed, at the time when it is set in the orchard. The tree then becomes practically a cutting, and it will begin at once to throw out the necessary supply of young and active roots, with a top to correspond. The practice of Mr. Stringfellow is to leave only an inch or two at the base of the old root, to furnish surface from which new ones will put forth.

In order to determine whether the method would be suitable for this climate, an experiment was begun on a small scale last spring, in which four trees each of standard and dwarf Pears, Early Richmond Cherry, German Prune, Peach and Quince, were selected for trial. The trees were two years old and as even in size as it was possible to get them. Two trees of each of these varieties were pruned so that not more than an inch or two of the roots remained, and the tops were entirely removed, leaving only a stick. A hole made with a two-inch stick was all that was needed in setting them out.

The other two trees were planted in the ordinary way, leaving the entire root-system. Before planting, the trees were all photographed, and after they had completed the season's growth they were taken up and again photographed.

The result of this experiment showed that the Peach was capable of producing a magnificent root-system and a top to correspond, even after being deprived of all its roots and branches to begin with. The dwarf Pear also made a fine growth, producing a finer root-development than the trees which were not pruned. The standard Pear was not quite as good, and the German Prune and Cherry were next in order. The Cherry made very little growth, barely enough to maintain life. The Quinces both died.

While this experiment shows results favorable to close root-pruning, it must be borne in mind that the season was exceptionally favorable for this work, as there were timely rains throughout the growing season. A dry season might produce entirely different results; for that reason we shall continue the experiment for a series of years and on a larger scale; so far it simply shows what these trees will do when treated in this way under favorable conditions.

La Fayette, Ind.

J. Troop.

### The Hellebores.

IT is the intention of these notes to mention more especially the true garden Hellebores or varieties of *Helleborus niger*, commonly known as the Christmas Rose, but as there are several plants grouped together under the common name of Hellebore, and as some of these have been the means of bringing these beautiful winter flowers into bad repute, it may not be time wasted to consider the synonymy of these popular names.

In the first place, the *Helleborus niger* has no part in the composition of the insect powder sold under the name of Hellebore powder. This is made of the *Veratrum album*, or White Hellebore, as a basis, its properties of destroying caterpillars being well known. The North American species, *V. viride*, is also used, but is said to be less effective in results. The Winter Hellebore is the pretty little *Eranthis hyemalis*, or Winter Aconite, and there are two Orchids from which the French Helleborine is obtained, namely, *Serapias lingua*, a native of south Europe, also another Helleborine obtained from the genus *Epipactis*. Thus we see that under one generic term, Hellebore, we have plants that represent three distinct families, and this is a good illustration of the futility of popular names for plant identification.

*Helleborus niger* is so called from its black root-stock; it is the Christmas Rose of gardens because it flowers at that season if given treatment so that its flowers may expand at mid-winter without the blighting influence of severe frosts such as we experience in New England. In the latitude of New York I have grown these plants and had them flower admirably out-of-doors, though only in certain seasons. It is far better, however, to grow them wholly in frames, where they can be shaded in summer from strong sun, for if left undisturbed in such a situation, and protected in winter from cold, there is no difficulty in having flowers of spotless purity at Christmas, when they are most acceptable. It is possible that in the near future we shall see them grown in great quantity for the Boston market, as some of our commercial growers are preparing to have them in quantity, for only in this way can an impression be made. There is every reason to believe that the venture will be a success by having enough plants to lift half each year to produce a crop of bloom and let them rest the year following while taking in the other half.

Of *Helleborus niger* there are at least half a dozen well-marked forms cultivated in gardens. There is the narrow-leaved form, *Angustifolius* of English gardens, and another similarly named of Scotch origin, the latter having its white flowers tinged with rose. *Altifolius*, also called *Maximus*, has flowers five inches across, and often three on a stem. There is, too, an intermediate form known as *Caucasicus*, the still better-known *Madame Fourcade*, with snow-white petals, and lastly, *Major*, which rivals in size the giant *Altifolius*. Thus it will be seen that a collection of the form of *H. niger* alone make a most interesting group in themselves, and are really decorative subjects for the winter season when a little care is taken to supply their needs. It may be said of the whole genus that they dislike disturbance at the root more than most plants do. After division or removal it is often a year or two before they fully recover, hence the need of either planting in pots for plunging or frame treatment all the year, as noted.

Besides the true Christmas Rose, there is another section of the genus that has been developed from the different species

that are scattered all over Europe and extend into Asia Minor. There are about ten species from about as many different countries, and under garden culture a race of plants has been produced which are much superior to the species themselves. Of these the best are F. C. Heineman, Frau Irene Heineman, Apotheker Bogren, Doctor Schleicher Albin Otto, W. Schmidt, Commerz, Benary and Hofgartner Hartwig. These are all of German origin, and with their species flower about Easter-time in the open ground; it is possible to grow them out-of-doors the year round if a little protection is given to the ever-green foliage in fall in the way of dry leaves or hay to help collect the snow round the plants. They are, indeed, very suitable for planting as an undergrowth for trees or shrubs that would furnish shade in summer, while they do not rob the soil of so much moisture as to impoverish the Hellebores. A good soil rich in vegetable humus is well adapted to their growth; a top-dressing of leaf-mold will best aid in keeping the plants in vigor, and it should be left as a mulch rather than spaded in and mixed with the soil, as there is danger of disturbing the roots by this operation.

Two species of Hellebore are found wild in Great Britain, though possibly not indigenous. *Helleborus foetidus* is of a semi-shrubby habit and a plant of great decorative value on account of its fine foliage effects in winter; the other species, *H. viridis*, is similar, and both have green flowers that are the least desirable feature of the plant, their foliage being more ornamental.

Hellebores bear seed freely, and this may be sown preferably as soon as ripe, or some time will elapse before the young plants appear. But as both the winter and spring flowering sections cross readily, it is possible by forcing one and retarding the other to hybridize the two sections and get very desirable plants. Strong plants are readily separated, and this is the best way to increase any desired variety.

South Lancaster, Mass.

E. O. Orpet.

### Pandanus.

FEW plants are more useful or better known than *Pandanus*. *Veitchii* and *P. utilis*, though it is hardly clear why these are so generally grown, and other distinct and beautiful species of the same genus are neglected. True, these two species will endure more hardship, but some others are equally good decorative plants. *P. ornatus* is a handsome species with rather broad, bright, shining green leaves, furnished with white spines. The marginal spines are strong, but those along the midrib are somewhat minute. The leaves are more erect than those of *P. utilis*, and their growth is not quite so rapid. *P. glaucus* grows compactly and has shining bluish-green leaves, furnished with white spines. *P. laevis* is a tall-growing species with the screws occurring closely; the spines are sharp, brownish green, the lower ones on the midrib curved, and often alternately recurved. *P. Pancheri* looks much like a green *P. Veitchii*, only the leaves are narrower. *P. Javanicus variegatus* is one of the most beautiful of all the varieties; the leaves are long, narrow and somewhat drooping; the ground-color is bright green, with bands of white traversing the entire leaf.

These are a few of the more distinct forms, and all are of comparatively easy cultivation. Screw Pines (as they are commonly called) seldom flower under greenhouse treatment or until they have attained considerable size, so that it is hard to procure seed from this source, though seed of the more commonly grown sorts can usually be procured from seed stores. But this method of increase is seldom resorted to, as offsets are easily procured from most of them. The offsets should not be taken at too small a stage; they root quite readily, but the crowns must be kept well up to avert the danger of damping. They may be inserted in an ordinary propagating-bed, or singly in small pots in a mixture of sphagnum and sand, and potted on when well rooted. In shifting large plants it is a good plan to use some antidote to acid in the compost, such as charcoal, as there is nothing so injurious to these plants as sourness in the soil. Large shifts or frequent repotting is unnecessary, as they need comparatively little root-room in proportion to the size of the plant, but when potting they should be set well down in the pots, as they incline to push themselves up out of the soil. Roots are quite freely sent out from the stem at the base of the old leaves, and in their downward course they sometimes need to be guided a little so that they will not run outside of the pot. Some soft tying material should be used, so that there will be no danger of cutting the roots. Some growers do not syringe during the winter months, as the water is apt to accumulate at the axils of the leaves and cause decay, but if a minimum

night temperature of sixty degrees can be maintained and fresh air often admitted, there will be little danger from this source, and an occasional syringing helps to keep the plants clean. The most injurious insect enemy is scale, which quickly disfigures the leaves if allowed to get a footing. But these plants are not particularly subject to pests. An occasional sponging with water and whale-oil soap is a preventive. To bring out the true characters of the variegated forms the plants should be kept moderately shaded. If exposed to strong light the colors lose their brightness to a considerable extent, the white assuming a greenish hue and the green becoming lighter.

A plentiful supply of water is necessary during the summer months, but in winter less is required, unless the plants are exposed to the drying influences of fire-heat and the lack of atmospheric moisture. These conditions should be avoided as much as possible, as they do better in a moist atmosphere.

Tarrytown, N. Y.

William Scott.

Onions.—Every one who has adopted the plan of sowing Onion-seed in boxes and then transplanting the young seedlings, is convinced that in one respect this is preferable to the old way of sowing the seed in drills where the plants are to remain. Not one-sixth as much seed is needed as with the old method, and the little labor involved in pricking out the young plants is more than offset by the great saving of time in weeding and thinning under the old system. Hardly any manual work in the garden is more troublesome than weeding among small Onions, but when the ground can be cultivated several times before they are set out many of the weeds are killed, and, besides that, the young plants are of a sufficient size to be seen, and there is less trouble in working among them. By the new plan, as it is called, although it has been practiced for a good while by individuals, an even crop is always assured and the plants are less liable to attacks from cut-worms and wire-worms. We sow the seed about the middle of February in ordinary seed-boxes, with a compost of loam with dried and pulverized manure, and we set the boxes on the shelf of a cool house. About the middle of March these boxes are transferred to the frame and the plants are hardened off gradually. The young plants are set out early in April in rows two feet apart and six or eight inches between the plants, according to the variety. Where space is valuable the rows may be left eighteen inches apart, but it is much more easy to cultivate between wider rows. Every variety I have tried is improved by transplanting, and all mature earlier than when they are treated in the old way. Our best keeping varieties as well as our best-flavored ones last year were Prize-taker, Ailsa, Craig and Cranston's Excelsior. The two last-named are superior English varieties. Silver King and Giant Rocca will grow to enormous size under this treatment, but they are not good keepers. For a general grade we use Yellow Danvers and Red Wethersfield. As a rule, white varieties do not keep well, the best we have tried being the Queen.

Taunton, Mass.

## Correspondence.

### The Choke Cherry in Cultivation.

To the Editor of GARDEN AND FOREST:

Sir,—Recent notes in GARDEN AND FOREST, as well as other sources of information, seem to indicate that the Choke Cherry is unknown to cultivation. Such is not the fact, although its use is apparently limited and local. One of the earliest recollections of my boyhood has to do with two or three Choke Cherry trees beyond the garden in the edge of the old orchard, and I can almost feel their pucker yet, and I recall the feeling of danger when some older companion would utter the grave warning never to drink milk after eating choke cherries. These could hardly be called cultivated choke cherries, however, and the trees were simply spared where they had chanced to spring up.

In distinct contrast with this puckering little fruit I call to mind another kind, always spoken of as the "tame" choke cherry. The merits of this fruit may have seemed greater than the reality, since none of it was to be found on our own farm. Still, any boy would call this fruit good, and when prepared for the table boys still call it good, no matter what may be their age. The botanical characters of the tree appear to be the same as those of the wild Choke Cherry, *Prunus Virginiana*, though the tree reaches a larger size than that commonly reached by the shrubs along the fence rows. In this cultivated form the trunk often reaches a diameter of from

four to six inches, and the tree attains a height of fifteen to twenty feet.

The fruit is much larger than in any wild forms which I have seen, perhaps ranging from three-eighths to half an inch in diameter. It also has much less astringency, and whatever remains of this entirely disappears with cooking. The fruit is much used both for pies and sauce, and is also canned for winter use. Any criticism as to its quality in these forms would be that it lacks in pronounced flavor rather than that it possesses any strong or unpleasant ones. It does not make a rich sauce, but one which is, on the whole, very cooling and agreeable.

It is not necessary to cook the fruit in order to dispel its astringency. Those most familiar with its use have learned that when the fruit is fully ripe, if it is put into a cloth sack and rolled back and forth or shaken in a closed vessel, this quality disappears. Treated in this way and served with sugar and cream, like peaches or other fresh fruit, it is a dish by no means to be passed by. I do not remember that the fruit was ever used for jelly, but, of course, it might be and perhaps is.

There are certain qualities possessed by this fruit which seem to make it worthy of being better known than it now is. In the first place, it ripens at a time when other cherries are gone. Furthermore, the tree is uniformly productive, seldom, if ever, failing to yield a crop. Although small, the fruit is borne in clusters, so that it is quickly and easily picked. It also has the quality of remaining a long time on the tree after ripening, which is a desirable feature for home use. The tree is apparently well able to care for itself, for all of those which I have observed have been growing absolutely without care. It seems further that it must have few serious enemies, otherwise it would not prove so uniformly productive. As to its longevity I cannot testify. Among the trees of my earliest remembrance several are gone, while others, when I last saw them, were still yielding their annual crop of fruit.

The chief objection against this little recognized claimant for admission to our gardens is its small size and the consequent number of pits. If the suggestion of one of your correspondents for a pitting machine were to take tangible shape it would add greatly to the importance of this fruit. Indeed, there seems to be no reason why such a machine should not be as readily devised for cherries of this size as for larger ones. It is possible that the same machine might answer for both, for in size these fruits are about intermediate between the wild choke cherry and the Early Richmond. As commonly served the pits are left in, and in that case it becomes largely a question of leisure, for while they are easily removed it takes time to do it.

So far as I have learned the history of this fruit from inquiries made in northern Pennsylvania where I have known it, the original trees were brought to that region from Connecticut by one of the older settlers. The trees sprout from the roots to some extent, and these sprouts have served as a means of distribution in this farming community, so that it is not at all an uncommon fruit in that immediate vicinity. As to its remoter history I know nothing. Probably it is merely an improved form originally selected from some hedgerow. The variation in size of fruit which these wild groups present certainly lends color to such a supposition.

University of Nebraska.

Fred W. Card.

### Notes on the Hybrid of Maize and Teosinthe.

To the Editor of GARDEN AND FOREST:

Sir,—In the American Museum of Natural History, New York City, there is an ear of corn displayed in the room on the ground-floor at the left-hand side of the main entrance which was collected by Carl Lumholz, the explorer, among the timid Tarahumara Indians of Mexico. It is identical in all respects with the form which I described in GARDEN AND FOREST (vol. ix., page 522), as produced by crossing, for three seasons successively, Teosinthe and Maize. It is interesting to note the occurrence of this form among a wild tribe which comes little in contact with white men.

Dr. Nicolas Leon, of Mexico, informs me that this hybrid is encountered among the Mixes and the Zapotecs inhabiting the state of Oaxaca, and that there it is called Maiz de los gentiles.

Another interesting fact concerning Maize and Teosinthe is one made known by Dr. William Trelease, of the Missouri Botanical Garden. It is well known that Corn smut, *Ustilago Zea-Mays*, fastidiously confines itself to the Maize-plant, being found on no other plant. Dr. Trelease discovered that it also grows parasitically on Teosinthe, a fact which also points to the close affinity of Maize and Teosinthe, if they are not identical.

University of Pennsylvania.

J. W. Harshberger.

## Meetings of Societies.

### The Nebraska State Horticultural Society.

THE twenty-eighth annual meeting of this society, recently held at Lincoln, was devoted largely to forestry and landscape-gardening. In the first paper presented, Mr. Peter Youngers, of Geneva, spoke of the trees which had proved especially adapted to the conditions and climate of Nebraska. The American Elm leads all other trees as a shade-tree for that state, although, of course, it is not as good as some others for its timber. The Honey Locust and the Green Ash have been almost universally satisfactory, while the Scotch and Austrian Pines in their younger stages are thrifty growers. The Black Walnut flourishes in moist soil, and the wild Black Cherry makes a rapid growth for a hardwood tree, although it has suffered from sun-scald during recent dry years. There has been an astonishing mortality among Mulberry-trees during these same dry years. Mr. Harrison, of Weeping Water, also spoke in high terms of the Honey Locust, especially for its power of resisting drought.

Dr. C. E. Bessey, in speaking of the distribution of the forest-trees in the state, defined native trees as all those which were found here by white settlers, although it is possible that the Indians may have introduced some of these. *Pinus ponderosa* has come down the streams from the west, and remnants of these trees are found much farther eastward than they now grow. Some discussion about the Diamond Willow followed, and persons most familiar with the woodcraft of the state were evidently not ready to relinquish their belief in this tree as a distinct type or species. Many others thought that its peculiar formation is due to individual peculiarities or the work of insects. Dr. Bessey gave an interesting account of the range of most of the well-known trees of the state, and, among other things, he stated that the Hickories have had a very hard time in Nebraska, and for the most part only creeping up the streams a little way.

Professor F. W. Taylor made a trip through Russia last summer, and in speaking of horticulture in that country he stated that little fruit is grown in the latitude of St. Petersburg—a few strawberries and fewer bush fruits, and no apples whatever. The latter fruit is hardly seen as far north as Moscow, although the traveler going south begins to come into the region of cherries at this point. The Cherry-trees are all short-lived, grown on their own roots, and new sprouts are allowed to come up about the base to take the place of the old trunk as soon as that fails. It is not probable that these trees would last ten years in the climate of Nebraska, being all dwarfs of the English Morello type. Russian varieties of Apples are very local, and they are poor, as a rule. There are no great nurseries which serve as centres of distribution, and therefore these varieties are confined largely to the immediate sections where they originated. This is the reason for the confused and hopeless state of the nomenclature of the Russian fruit-trees which have been sent to this country. No doubt, some of these Russian fruits have enabled the farmers of the northwest to grow some kind of an apple in a more trying climate than would have been possible with our ordinary varieties, but the more we know of the Russian Apples the less we find in them of value.

Dr. Ward talked in an entertaining way of the impressions which he had received of the forest-gardens of the Harz Mountains. This region is some fifty miles long and half as broad, and one who looks from the summits of the ranges is impressed by the smoothness of the landscape and the checker-board appearance of the woods made by the alleys running between forest blocks. These alleys run perfectly straight without regard to the contours of the land, and are kept clean and free from all vegetable growth. The squares are of different sizes, but all the trees in the same square are of the same size. For a small fee people have permission to gather limbs or forest material from the ground, but no axe is allowed to be taken into the woods. A cart for carrying away the collected material may be brought and left at the roadside, but cannot be taken into the forest. Trees to be cut are marked by the forester and the measure is recorded, so that when the wood is piled up at the roadside the amount must correspond with the measurement. At various points selected with reference to their soil and aspect there are clearings for the homes of the foresters surrounded with beds of forest seedlings. The woods are very carefully protected against any intrusion, no one being allowed to light a fire anywhere, with no smoking even in the grass by the roadside, and no hunting except by Government permits issued to the foresters and to individuals at a certain fee. Visitors, however, can go where they will,

and even in places where there are fences to keep the game there are gates to admit passing through. Good roads are necessary in good forestry, and therefore there are public highways through the forests, macadamized, well-drained, carefully guttered, and having easy grades. These are kept in perfect condition, swept and raked after rains, so that nothing remains on the surface. Besides these there are ordinary dirt roads, carefully laid, beautiful footpaths two or three feet wide, and railroads provided for travel through the mountains, even where their construction has not yet been needed.

Professor Card spoke of landscape-gardening as a fine art which ranked with painting, sculpture and architecture, and after a brief historical sketch he said that the work of the landscape-gardener was to produce nature-like effects—that is, to compose a picture which interprets nature rather than one which imitated nature slavishly. A landscape-painter can vary the forms of his trees to meet the demands of his picture, can introduce a mountain background or a wandering stream, but a landscape-gardener is held in by stricter limitations. He cannot even select a single point of view, as the painter can, but must present his picture from every direction. Besides this, the painter completes his picture as it is to remain forever, while the gardener must work with constantly growing materials in such a way that they shall always be presentable, and, if possible, so that they should always improve. Professor Card's lecture was illustrated by lantern slides, which showed the qualities of some of our best trees; some examples of ancient topiary work, and the accomplishments of some of our modern expensive styles of carpet-bedding, contrasted the freer forms of natural planting. Pictures were also exhibited to show how highways, school-grounds, cemeteries and home-grounds could be made more attractive.

Mr. J. A. Hogg, in giving his experience with orchards in the south-central part of the state, said that the trees in that section were headed low (1) to prevent hail from striking the body of the tree, since borers are likely to enter wherever the bark is bruised; (2) to prevent sun-scald; (3) to protect the roots from the sun's heat; (4) to protect the tree against wind so that the pollen will not be blown away nor the fruit blown off; (5) to make fruit-gathering easy. The best fruit in that region is found on the lower limbs of the trees. In gathering cherries it is oftener necessary to lift up the limbs than to use a ladder to reach them. Russian Mulberries and Honey Locusts, being free from insects and furnishing abundant nectar for bees, make desirable wind-breaks. On the north side of a Mulberry hedge, Currants, Gooseberries and June-berries will do well. A row of three-inch tile under every row of trees or bushes for the purpose of subirrigation has proved useful wherever tried.

Mr. L. M. Russell, in giving his experience with Peaches, said that he had sold 12,000 bushels last year, and that 3,000 more rotted on the trees owing to the ravages of a black fungus which was most severe on common varieties. He thinned away about half of this fruit and he ought to have picked off half of what remained. The trees are now planted fourteen feet by eighteen, although they were originally planted much closer. The Wright has proved their most profitable variety, although it is late.

Mr. H. F. McIntosh, of Omaha, in speaking of the horticultural press, said there were some forty publications in the United States nominally devoted to horticulture or some of its branches, but most of these belonged to the class known as "house organs"—that is, they are papers connected with and managed by commercial establishments. Many of them are good journals, and they can afford to be, since they offer an opportunity for the publishers to send out advertising matter at one-tenth of the postage which it costs to send out catalogues and circulars. About one-third of these publications have a circulation so small that it is not rated, and our very best ones are not liberally supported. Horticulturists especially do not support these publications as they should.

Professor Swezey, in speaking of the conservation of rainfall, says that the evaporation from the water surface at Lincoln last year was forty-four inches. The year before it was forty-eight inches. The reason for this great amount of evaporation is the dryness of the air, the windiness of the climate and the high temperature. Of course, where moisture is so much needed in the soil, every effort should be made to preserve it, and he repeated the reasons for surface tillage as a check to the waste of water.

Dr. Bessey advocated attempts at reforesting the sand-hills of Nebraska, which, in fact, were not all sand. The valleys between the ridges formed pockets with little ponds of water in wet times. The sand in the hills is not always drifting sand and it is not always poor. The hills are covered with grass, and this is heavy in the valleys. There are wild Plum-trees in

the moist spots, and the Lead-plant is often found on the slopes. The grass is never dense, but is tenacious enough to hold the sand from blowing, and furnishes a large amount of pasturage. There are remnants of former Pines scattered over the regions which are not all worthless land, and should be made more useful. The valleys are very rich, but when the sod is broken on the hills the sand begins to drift. Dr. Bessey thinks it ought not to be more expensive to start a productive forest in these sand-hills than it was to cut away the forests for agriculture in the older states. Pine timber grows on thinner soil than this in Michigan, and there seems to be no reason why it should not grow here after it is properly started. Altogether he considers the problem well worthy of state or government investigation.

## Recent Publications.

*A Popular Handbook of the Ornithology of Eastern North America*, by Thomas Nuttall. Second revised and annotated edition. By Montague Chamberlain. With additions and one hundred and ten illustrations in colors. Little, Brown & Co. 1896. 2 vols., 8vo.

Nuttall's fame, though resting mainly on his botanical writings, owes much to the *Manual of Ornithology*, the first volume of which appeared in 1832 (with an enlarged edition in 1840) and the second in 1834. The cause of the popularity that this work immediately obtained is not far to seek. It was the first handbook of the subject, and presented it in an extremely attractive manner, combining a sufficiently scientific account of our ornithology, with a series of charming sketches of bird-life that have rarely been excelled. The work had been long out of print, when in 1891 the publishers decided to issue a new edition, and Mr. Chamberlain was entrusted with its preparation. The work before us is a revised issue of this edition, with a few changes and additions, including the introduction of the colored plates.

The classification and nomenclature of Nuttall's work have become antiquated, and many new species have been added to the list of our birds since he wrote. In the new edition it was decided to intercalate descriptions of these additional species and to give such information about the others as had been acquired since Nuttall's day. At the same time it was deemed advisable to exclude a few species occurring only west of the Mississippi, thus making a complete handbook of the ornithology of the eastern faunal province.

These variations from the original work are clearly indicated by typographical means, and come within the scope of editorial function, but one would have supposed that Nuttall's text in other respects would have been reverently treated. A comparison, however, of this edition with the original shows that many liberties have been taken. Whole paragraphs have been omitted in many of the biographies, with nothing to indicate such omissions. In fairness it must be added that these excisions have been judiciously made, and nothing of real importance has been lost, but when one finds that such things are done he cannot help feeling that he is being treated to a *réchauffé* from which, while he may praise the cook, he cannot trust himself to judge the flavor of the original dish. Against such a mode of serving a classic we must protest.

But, apart from these considerations, the work is an excellent guide to the study of our birds. Mr. Chamberlain's notes, though not copious, are sufficient to put the student in possession of what he should know of the recent studies in the subject, and his additional biographies are faultless. The handsome typographical dress makes the volumes a delight to the eye, and the colored plates, made up of figures copied mostly from Audubon and Wilson (though this is nowhere stated), add to the attraction of this revised issue. It merits, and will doubtless find, a wide circulation.

## Notes.

We have often commended *Kœlreuteria paniculata*, an ornamental tree of the second size, for its graceful foliage, especially in the earliest stages of its growth, and for its abun-

dant yellow flowers in midsummer. *Meehans' Monthly* adds to this commendation that in the fall of the year its rich crimson foliage vies with that of many of our American trees which have been celebrated in this respect. We should like to hear from correspondents, especially from those living south of this latitude, whether the leaves of these trees with which they are familiar take on this rich autumn color. We have not observed it in trees about here.

A cold wave has once more left the northern part of Florida covered with ice. So far as can be learned at this time the disaster to Orange groves was not nearly as sweeping as the great freeze two years before. Indeed, there were comparatively few trees in bearing, although in the old groves which were cut to the ground, root-sprouts have already reached a height of ten to fifteen feet. Prudent growers early in the winter wrapped the stems of these young trees with Palmetto leaves, straw and burlaps, which must have proved a great protection; and those who had not already taken this precaution had ample time to protect their groves after the weather bureau had warned them of an approaching cold wave. Fortunately, the low temperature was only of short duration. The extreme of cold was reached at six o'clock of last Thursday morning, and by nine o'clock the weather was rapidly moderating all over the state. No doubt, exposed buds and foliage were frosted, but let us hope that next year's crop will not be sensibly diminished. The blow was most severe upon the growers of early vegetables for northern markets. Throughout the northern part of the state truck-farms will need to be generally replanted.

Professor Georgeson, of the Kansas Agricultural College, in offering to send samples of the Soy bean to farmers of that state, gives in *The Industrialist* some account of the experience with this crop, of which several acres have been grown on the college farm for the past six years. Even in the years of severest drought the crop has not failed completely, and last year a yield of sixteen bushels an acre was harvested on the 31st of August, from ground seeded on the 19th of May. This crop is especially valuable since it can be grown on stubble-ground from which wheat and oats have been harvested and a fair yield secured. In feeding value the Soy bean takes precedence of linseed-meal, and is more valuable than any other concentrated food that can be found in the markets except cotton-seed meal, and this is sometimes poisonous when fed to pigs. The Soy bean contains two and a half times as much protein and five times as much fat as wheat bran, and it contains a greater percentage of protein than linseed-meal, and twice as much fat. Soy Beans are planted in rows thirty-two inches apart, and they are cultivated a few times to keep down the weeds and retain the moisture in the soil. Altogether this bean is one of the most promising of the additions to farm crops for the middle west, and it is likely to be more and more valued as its virtues are understood.

Last year three species of *Xylina*, commonly known as green fruit worms, large, light green caterpillars, did a great deal of damage to the apple crop by eating holes into the sides of young fruit in May and early June. These caterpillars are from an inch to an inch and a half long, and they have not appeared in dangerous numbers in the region infested this year since 1877. They begin to eat one side of the fruit, and continue until something like half of it is eaten, and then go to another one, thus injuring several fruits. They are not found on the trees after the middle of June. Fortunately, these caterpillars are inviting to the birds, and they suffer from parasitic insects, so that it is not certain that they will appear in dangerous numbers another year. Their attack would have been a serious matter last year but for the unusually heavy crop of apples throughout this state. After they begin to eat the apples there is little use in spraying them, but if the trees should be sprayed at least once, as is always advisable, with Paris green and Bordeaux mixture before the blossoms open, some of the worms might be killed. After the fruit sets the only successful and practical way of fighting them is to jar them off into sheets, as is done with the curculio. The soil should then be thoroughly cultivated during the summer, for this will kill many of the insects which are undergoing their transformation. Bulletin No. 123 of the Cornell Experiment Station, by Professor Slingerland, is devoted to this pest.

Newtown pippins, at forty cents to one dollar a dozen, are seen in some of the fruit-stores. Winter Seckel pears may be had for sixty to seventy-five cents a dozen, Winter Nelis at seventy-five cents to one dollar, and Easter Beurrés for \$1.25. Large and bright-colored hot-house strawberries find buyers at

\$2.00 a cup, and well-grown Lady Thompson berries, from Florida, neatly laid in oblong splint baskets holding more than a quart of the selected fruit, cost \$1.00. Most of the Florida strawberries have been immature, lacking in color, and without much demand. Some forty boxes of mangoes were recently received from Jamaica by a wholesale merchant. Retail sales are almost entirely confined to former residents in the West Indies, though the distinctive fragrance of this stringy fruit tempts occasional buyers to try it as a novelty. New limes are coming from the Bahamas. A novel display in one of the fruit-stores was a bunch of grape-fruit, six of the heavy fruits closely clustered together on one stem. Florida Russet oranges now sell at wholesale for \$4.00 a box, and "brights" for \$4.50, though higher prices are occasionally asked by some foresighted dealers as the end of the season is approaching. Florida grape-fruit, in the desirable sizes of fifty-four and sixty-two fruits to a box, costs as much as \$13.00, or nearly twenty-five cents each, to the retail dealer. The same sizes of Jamaica grape-fruit are quoted at \$8.00 to \$9.50 a box. Very large and extremely small sizes bring much less, especially the latter, which are prematurely gathered.

The snowy, sunless days of last week were accountable for a large stock of cut flowers of second and third quality, which were offered by the street vendors on Saturday, when milder weather set in. Roman hyacinths and lily-of-the-valley, looking chilled and drooping, sold at ten cents for a bunch of less than a dozen stalks, three or four Meteor roses also brought ten cents, and small bunches of violets cost twenty-five cents. But these low-grade blooms are at best an unsatisfactory suggestion of the fresh and delightful flowers shown in large variety in the stores. White snapdragon, great spikes of mignonette and smaller ones of ordinary varieties, pansies, candytuft, jessamine and strikingly beautiful blooms of a large strain of Marguerites were displayed in one of the Broadway windows on Saturday, together with cut branches of the delicately foliaged and flowered *Acacia dealbata*. Single hyacinths of graded shades of lilac and purple, pansies, forget-me-not and the yellow variegated Bouton d'Or carnations, white and purple lilacs, and the orange and scarlet fruits of Bitter-sweet were all represented. The double flowers of Marie Louise violets sold for \$1.00 a bunch, and the large single California violet, of rich color and fragrance, in bunches of twice as many flowers, was in demand at \$1.50. Bridesmaid, Bride, Meteor, Mrs. Pierpont Morgan and Madame Cusin roses sold for \$2.00 to \$3.00 a dozen, and perfect buds of Souvenir du President Carnot for \$4.00 to \$6.00, with specially well-grown ones at \$8.00. Plants of Azalea, densely flowered, are becoming conspicuous features in the show windows.

There will doubtless be a scarcity of green vegetables during the next few weeks, owing to the frozen crops in Florida, but California, Bermuda and Cuba have already been drawn upon for string-beans, and other new vegetables will soon come from the southern Atlantic states. On last Monday southern supplies were greatly shortened and prices had advanced considerably. Bunches of new kohlrabi and beets, from Florida, cost ten cents each, string-beans were twenty cents a quart, and tomatoes twenty cents a pound. Peas have doubled in value within a week, and now command \$3.00 a peck. The last consignments of southern lettuce realized ten cents a head, but the hot-house supply of this vegetable, from Boston, is abundant, and prices have been as low as fifty cents for a dozen heads within the past few days. New carrots, from Bermuda, cost ten cents a bunch; parsley, peppers and Romaine lettuce come from the same islands, as do onions and potatoes, the latter worth forty cents a half-peck. Cauliflower comes from California by the car-load, and retails at twenty-five to thirty cents a head. Okra, from Cuba, costs ten cents a dozen. Small French radishes, grown under glass near by, bring five cents a bunch; hot-house tomatoes, forty cents a pound, and forced rhubarb, fifteen cents a bunch of a half-dozen stalks. Boston cucumbers readily bring thirty cents each in the entire absence of the southern product, and in some of the high-class fruit-stores they are each wrapped in oiled tissue-paper. Hot-house asparagus is also carefully wrapped, and that from the west sells for seventy-five cents a bunch, while the stouter and longer stalks from New Jersey cost \$1.00 for a bunch of about twenty shoots. French artichokes come from Europe regularly each week, as do Brussels sprouts, the latter costing twenty-five cents a pound, while the native sprouts cost twenty cents a quart. Mushrooms have been unusually plentiful and cheap, the best selling at sixty cents a pound.

## Abandoned Farms.

At a Farmers' Convention, held not long ago at Danbury, Connecticut, Mr. R. S. Hinman read a paper on "The Deserted Farms of New England," in the course of which he presented some novel phases of the problem which has caused so much discussion. It was admitted that there are deserted farms in Connecticut, but in the first place much of the land which has been abandoned ought never to have been cleared or tilled. As an illustration of this statement Mr. Hinman referred to one cold field facing the north-west and so full of fast rocks and bowlders that it would be hard to turn in it a straight and continuous furrow for a rod, while the scanty soil between the rocks is thin and sterile. A man now living remembers that in his youth he had planted this field with Corn on shares, and both he and the owner of the land were content with the crop and its cost; but the field has never been tilled since and will not be tilled again until men are content with wages of fifty cents a day while boarding themselves. In contrast with this, Mr. Hinman admitted that there are lands in the state which are easily tilled, readily accessible and apparently once productive, which have long been allowed to grow up to brush. In explanation of this he argues that the very fact of easy tillage and access wrought ruin to the land. The owners took crop after crop from it and returned nothing, because the process was temporarily profitable, until finally the available plant-food was exhausted. Then the cost of enriching the soil with fertilizers to the point of profitable productiveness was so great that the crops would not pay for the raising when they came in competition with those grown on cheap new western land.

But, besides rough and sterile lands and lands which have been rifled of their fertility by covetous owners, it is further admitted that thousands of acres of excellent pasture-lands have been abandoned to Hardhack and Blackberry vines, because Connecticut farmers preferred to lend their money to western competitors at eight or ten per cent. interest, rather than hire men to cut the brush and keep their farms in good heart for the future. When Connecticut passed a law allowing the registration of notes and bonds at a low rate of taxation, the farmers in one town of Litchfield County filed evidences of \$60,000 loaned to

western farmers. If that money had been used to improve their roads and enrich their lands these farmers might not have received ten per cent. on their savings, but they certainly would have had an investment safer than many western mortgages have since then proved. The plain statement of the case is that instead of using some of their savings to make their farms more productive, eastern farmers furnished working capital to their competitors, who naturally undersold them in their own markets and then never repaid the loans which gave them their start. Again, many an owner of a small farm found out years ago that he could make a better living in the city than at home, and although the land can be sold for a fair valuation the owner prefers to let it lie as an investment, in the hope that it will some day be worth still more, as will probably be the case if it is near a thrifty town or has some attractiveness of location.

It is to be remembered also that more people were needed to raise the same crop on the same land fifty years ago than are needed now, and that while horse-rakes, cultivators and mowing-machines take the place of men in the field, they do not need farm-houses to live in, and this accounts for the remains of a cellar and perhaps the remnant of a Lilac-bush, often seen along the roadside, to testify that here was once a home, where now there is none. These little farm-houses all over New England were once occupied by shoemakers, wheelwrights, tailors or people engaged in other home industries that are now carried on exclusively in cities and towns. This does not imply a diminishing population; it simply means that the concentration of all these mechanical industries in the villages makes fewer houses necessary on the farms. These old-time artisans could keep a cow and a horse, and by making boots or mending chairs at odd spells could live on land which would not of itself suffice to support a family. That they have left these farms simply means changed conditions, and not necessarily any deterioration in the number or general comfort of the population. And, finally, there is now and then a deserted farm-house which is fit for occupation and a deserted farm upon which a living can be made, but this is because the owner leaves it for his pleasure or his profit and does not choose to sell. Very few farms have been sold under mortgage, and where farms have been taken by foreclosure, this, according to Mr. Hinman's observation, has always been under conditions that would have produced the same result in whatever business the owner was engaged. That is, the number of farmers who fail because they conduct their business without adequate foresight, intelligence and industry is not proportionally greater than the number who fail in manufacturing, mining or commerce.

And what of the future? Very plainly the forests never should have been cut from land where nothing else will flourish. The natural suggestion, then, is that the best use to put these acres to now is to encourage a new forest growth upon them as the cheapest crop they will produce. Undoubtedly, if all the land in Connecticut that cannot be tilled with profit could be helped to reproduce its original forest cover this would not only help to furnish the needed wood-supply of the future, but it would add to the fertility of the remaining farm-lands by breaking the winds, mitigating hard-weather conditions and helping the supply of moisture. While it must be admitted that where hundreds of acres of soil have been made unproductive by careless cultivation, there must be a loss somewhere, Mr. Hinman does not consider the abandonment of many Connecticut farms a misfortune to the state. Gardens run to weeds, barns with rotting timbers and tumble-down fences, do not add to the beauty of a landscape, but whether the community will be improved by a new occupant who will restore the land to its former use depends on the character of the newcomer. No doubt, much of the land could be reclaimed—that is, if it were managed by the highest skill, it might pay men who are willing to live cheaply themselves and bring up their families cheaply. Mr. Hinman

cites examples where foreigners, every member of whose families—men, women and children—are productive workers, have taken possession of lands once abandoned. They do not need periodicals or books, because they do not read; they do not care for the conveniences that drove their predecessors into towns to get the advantages of schools and churches and libraries and social intercourse. But what do these peasant-farmers bring to the commonwealth? By cheap living and hard work they manage to undersell their neighbors. Perhaps this is an advantage to the community at large who buy farm products, but it makes harder lines for the average Connecticut farmer. Whether it pays to encourage the immigration of this class of agriculturists is certainly an open question. But Mr. Hinman finds that many abandoned farms are passing into the hands of well-to-do people who do not need to enter into the struggle as competitors of the hard-working farmer of to-day. Some of these men belong to the original stock who left the barren uplands of the state to accumulate fortunes elsewhere, and now they are attracted to the place of their birth by ties of sentiment. They relish their native air, and the old farms make summer homes for their families. And, besides this, there are many places in the state which have a quiet pastoral beauty, many others with strikingly picturesque features, and these are sought and bought for what they are, and not for the memories which cling to them. There is a tendency, too, among men of means, to get together landed estates of considerable size, not to speak of larger tracts for game preserves and experiments in forestry. Buyers of this sort will, no doubt, be welcomed, and, perhaps, they will feel that money invested in Connecticut real estate is better spent than in yacht-building or horse-racing. Even if they practice agriculture as an amusement simply, they are likely to benefit the laboring people in the neighborhood, and they are sure to make experiments with improved breeds of domestic animals and new methods of cultivation, from which observing neighbors will derive benefit. They may live on their newly bought acres only a portion of the year, but they can hardly fail to bring material aid and social improvement to the communities with which they come into contact.

No doubt, the reasons for abandoned farm lands presented by Mr. Hinman are every one of them genuine, and they account to a certain extent for the present condition of things. But, beyond and outside of them, every one must see that there is a continued and remorseless pressure upon agriculture which every eastern farmer feels. Whatever the reason may be, it is certain that the farming population throughout the middle and eastern states is stationary or actually decreasing in number, while the urban population is multiplying at a marvelous rate. The farmer, too, seems to be losing his relative rank as a social and civil factor in the commonwealth. How to prevent all this, and whether it ought to be prevented, are questions which do not come within our province. But it is in the line of our teachings to suggest that the sooner forests can be made to cover the bleak and barren hills of New England the better it will be for everybody. Few people realize how much the wood lot did to support the farmer in the old days. Years ago it was stated by a shrewd Maine man, Mr. Tom Ford, in the *Country Gentleman*, that although the New England farmer worked all summer to raise hay, oats, potatoes, corn, beef and pork he really received no fair wages for his work and laid up nothing from this source. It was the logs and bark from his wood lot, the staves and shingle stuff, the hoop-poles and cordwood that brought him all his ready money, and when his woods were cut away half his income was gone. No doubt, the best treatment of these abandoned hills, too steep and stony to till, is to help them to grow up again with Oak and Pine, for the protection and enrichment of the lands that are still worth plowing, and for furnishing a crop which the world will always need.

THE New York Commissioners of Fisheries, Game and Forests have made a preliminary report in which they urge with great reason that something be done to relieve the state from the anomalous condition in which its forestry work has been placed. New York owns a great forest preserve which it is little less than criminal to allow to go to waste. As a source of public revenue, and still more as an instructive example of what can be done under scientific management, this reservation should be put under the charge of skilled professional foresters to make it a model for our New World conditions, and be an object-lesson in forest economy for the whole country. Unfortunately, the state constitution actually forbids the use of the axe in any of "the lands of the state now owned or hereafter acquired, constituting the forest preserve." And this means that the men who made the constitution did not know that there was any such thing as rational or conservative forestry, or if they did know it, they felt that the people of this state were too ignorant to organize and develop any system of forest practice in an intelligent and scientific way, or that they were too corrupt to administer such a trust without official knavery. It is suggested in this report that inasmuch as it is proposed to purchase large additional areas of woodlands, a special appropriation might be made for acquiring some tract of virgin forest in the Adirondacks, to be set apart as an experiment station, where the practicability of carrying on scientific forestry work with profit might be demonstrated. We hardly see how this can be accomplished under the constitution, in which it is stated that this forest preserve shall be forever kept as wild forest land. Perhaps forest land purchased outside the limits of the so-called preserve might be exempted from the constitutional prohibition, and, if so, it is to be hoped that the legislature will take steps toward acquiring some woodland which can be made directly useful as a source of forest supplies, and still more valuable from an educational point of view. The Commissioners believe that with such an enterprise fully inaugurated, a forest academy, well endowed from private resources, would soon follow. If such a school could be located on the experimental grounds, where students could have an opportunity to see and practice systematic forestry, we should have the beginning of that trained corps of foresters which will be needed in the twentieth century, if we are to make the most of the forests of our state and of the forests of our rational domain, and of those owned by private individuals and corporations throughout the country.

#### The Visalia Oaks.

ONE of the finest groves of *Quercus lobata*, near Visalia, is known as the Mooney Ranch Grove, on the motor line to Tulare City, and about five miles distant. It is said to cover nearly 150 acres, and the illustration on page 55 gives a very good view of it. While most of the trees are about a foot or eighteen inches in diameter, there are enough of the old giants of five and six feet in diameter to give character to the woods, for one is never out of sight of several such trees, and often finds a group of a dozen or more which seem to occupy nearly the whole field of vision.

The plant in the foreground, which seems to be a tall white flowering shrub, is really a Milkweed, as it appeared in November, when the photograph was taken. It is one of the taller species, often four or five feet high, and grows abundantly in the foot-hills and the adjacent plain, having worked down from the Sierras. It is also found along the watercourses spreading through the Oak forests. I saw it from the car-window in several places as we crossed the Visalia country, November 18th of last year, but secured no specimens. These Asclepiads and a tall, spreading, very brilliant Sunflower, under the influence of October showers, had put forth immense numbers of small, late blossoms among the dry seed-heads and along the main stalk.

I did not find time to measure any trees accurately in the Mooney Grove, but there is a small grove of about forty acres a mile from Visalia, which ought to be owned by the town, and here, within a radius of less than two hundred feet, I took the girths of five trees at six feet from the ground, and they ranged from eleven to fifteen feet, and the heights ranged from fifty-five to ninety-four feet. One of the trees, an old one, with considerable branch-room, had a broad spreading top (the top broken off). Another was tall and straight, with a trunk without a branch for twenty-five feet. The height of some of these Oaks is surprising. They seem to have grown in great thickets, in windless places, and the need of light and air forced them straight upward.

The Oaks in this little grove grow on a very heavy alluvial soil, so rich in alkaline salts that the common Alkali Grass of the plains, *Distichlis maritima*, is all that covers the surface. The soil, unlike that in the Mooney Grove, is unfit for farming, but the place is very attractive, covered as the surface is with this coarse Bermuda-like Grass, and so green and golden in this November season. The Oaks themselves are of many colors, though every tree on the forty acres is a *Quercus lobata*, for some are nearly leafless, others show yellow foliage, and still others are various shades of green. The bark also varies from smooth to very rough, and from dark brown to ashen gray. The lower branches are sometimes drooping, like those of so-called weeping-trees, but they sometimes extend nearly horizontally, though the normal type of the older trees is especially upright, as shown in the photograph of the Mooney Grove.

#### Paradise Valley.

THERE have recently appeared in GARDEN AND FOREST two or three articles upon the flora of Mount Ranier, especially that part of the mountain known as Paradise Valley. It occurs to me that an enumeration of the flowers found in this wonderful little valley would be of interest, and since I spent some time in studying the botany of Ranier last summer I am pleased to undertake such an enumeration.

Paradise Valley is situated on the south flank of Ranier, at an altitude of from 5,000 to 6,000 feet; it is in a Government reservation, the Pacific Forest Reserve. The Reserve, the crowning feature of which is the great mountain, is in the Cascades of western Washington, and covers an area of thirty-six by forty-two miles. In it is, perhaps, the greatest glacier system on the continent south of Alaska. Several large rivers head in the glaciers, and between two of these, the Nisqually and Cowlitz, up among perpetual icebergs, Paradise Valley is situated.

I judge that the valley is from four to six miles long and from a half mile to two miles wide. Its outline is very irregular and its surface rough and rugged. But the interest and attractiveness of the valley lie not so much in its formation as in its covering. An alpine meadow could hardly be more beautiful. The valley is covered with a perfect carpet of flowers, excepting here and there a dash of snow, a rocky crest, or a grove of Alpine Firs and Mountain Hemlocks.

The background for the floral display is composed of two Dog-tooth Violets, *Erythronium montanum* and *E. grandiflorum*; the former is pure white, the latter with a tinge of yellow and rose. Along streams and bordering snowbanks acres of ground are literally covered with these flowers. The two species alternate in the floral design, seemingly without reason, so that we have now a spread of white, and next a cloth of gold.

In the drier parts of the valley, two Heaths, *Brianthus empetriflorus* and *Cassiope Mertensiana*, form the greater part of the display. The first is a span, or a little more, in height, much branched, and has its foliage almost hidden with umbels of rose-colored campanulate flowers. The

second is taller and has pure white campanulate flowers, borne singly, and nearly hidden by the leaves.

A pretty pale blue Aster, *Erigeron salsuginosus*, grows nearly everywhere. *Potentilla gelida*, a Buttercup-like flower, and fine Arnicas furnish an abundance of yellow. In the groves there are many mountain Rhododendrons, handsome shrubs, several feet high, with pure white funnel-shaped flowers. *Spiraea rosea* is a common shrub on the cliffs. There are several Saxifrages, three or four species of *Mimulus*, a common and pretty one being the little yellow Monkey-flower, *M. alpinus*. *Orthocarpus pilosus*, the flowered Painted Cup, is plentiful. A handsome Knot-weed, *Polygonum bistorta*, bearing a spike of pure white flowers, grows almost everywhere in the valley. Wild Heliotrope, *Valeriana Sitchensis*, with corymbs of fragrant pinkish flowers, is common. There is a profusion of *Anemone occidentalis*, the mountain Anemone, its curious feathery seed-tops reminding one of the beard of a mountain goat. Several Lilies are found. Green Hellebore, *Veratrum viride*, *Dodecatheon crenatum*, *Gentiana calycosa*, *Pentstemon Menziesii*, are all plentiful. A bright yellow Aster, *Erigeron aureus*, is found in the higher parts of the valley. Accompanying it are generally a lovely blue Lupine, *Lupinus Lyalli*, and *Polemonium humile*, a light blue flower with a yellow eye. On the rocks, in this almost the highest part of the valley, *Spiraea cæspitosa*, a silky tufted plant with an abundance of small flowers, forms a thick velvety mass that excludes all other plants. Tolmie's Saxifrage, *Saxifraga Tolmiei*, found a little higher up, forms similar mats. In the volcanic débris a Daisy-like purple Aster, *A. pulchellus*, is common. At this altitude the elements have dwarfed the Firs and Hemlocks into prostrate shrubs, with trunks greater in diameter than in height, their long, gnarled branches sprawling on the rocks. The alpine Juniper, *Juniperus communis*, var. *Sibirica*, is common here. *Spraguea umbellata* is one of the odd plants to be found here; its radical, fleshy, spatulate leaves rise from a thickened root, and its rose-colored flowers are borne in a dense capitate umbel of nearly sessile spikes.

Grasses and Sedges are common wherever plants can grow in the valley. There are several Ferns, an abundant pretty one being *Phegopteris alpestris*. *Protocæcus nivalis*, the Red Snow-plant, forms blotches of a gory hue here and there on the snow-fields. Wood and rock are covered always with Mosses and Lichens.

Now and then there is an alpine grove of *Tsuga Pattoniana*, one of the handsomest of all Hemlocks, and *Abies lasiocarpa*, the alpine Fir. These groves are very picturesque; the drooping, dark green branches of the Hemlock bending with festoons of Lichens intermingled with the pale green foliage of the stately Firs, with now and then an Alaska Cedar, *Chamæcyparis Nootkatensis*, make a beautiful picture for a lover of trees.

## Foreign Correspondence.

### London Letter.

**DENDROBIUM BANCROFTIANUM.**—This is a variety of the Australian *Dendrobium speciosum*, from which it differs in having thinner, shorter pseudo-bulbs, smaller leaves and shorter, looser racemes of white flowers, with a few spots of purple on the labellum. Messrs. Sander & Co., who have lately introduced it, and with whom it flowered a few weeks ago, say that it grows and flowers with much greater freedom than the type. They exhibited a plant of it last week bearing six flower-spikes, and it was awarded a botanical certificate. The type is a very old garden Orchid which grows well from year to year under ordinary treatment, but only rarely flowers. I lately saw some fine specimens of it which had been hung under a tree in the open air in July and August, and they had made exceptionally large pseudo-bulbs. When bearing its long fox-

brush-like spikes of fragrant flowers it is an attractive Orchid, and, indeed, it is worth a place in collections if only on account of its large pseudo-bulbs and fleshy leaves. *D. Bancroftianum* is also from Australia.

**MORMODES LADIUM.**—This is a new species, recently flowered in the collection of the Hon. Walter Rothschild, Tring, and named by Mr. Rolfe. It is very near *Mormodes igneum* of Lindley, figured in Lemaire's *Jardin Fl.*, iv., 330, the scape being erect, a foot long, bearing about a dozen large flowers, the sepals and petals colored dark red, the lip paler and yellowish brown. A variety, also flowered at Tring and named *luteum*, was shown last week and obtained an award of merit. It differs from the type in having bright yellow flowers. The two were introduced together from Peru. All the *Mormodes* are handsome-flowered Orchids, and were it not for the fact of their behaving badly under cultivation they would rank with the best of garden Orchids. *M. luxatum*, *M. Ocanæ*, *M. parvum* and *M. Colossus* are introduced from time to time, and for the first year or so afterward are features of English collections, soon, however, to disappear. We grow them along with their cousins, the *Catasetums*.

**ODONTOGLOSSUM CRISPUM STEVENSI.**—Baron Schroöder has, under this name, a plant which is generally considered to be the handsomest of the many select varieties of *Odontoglossum crispum*, and he exhibited it last week in finer condition than has ever been seen before. The spike was a yard long, gracefully arched, and it bore fourteen flowers, each five inches across, white, heavily blotched with reddish brown, the lip with a very large blotch in front of the crest. The size of the flowers and the richness of the markings are its most striking features. The plant has been in the famous Dell collection since 1886. The keen competition for the possession of these uncommon forms of *Odontoglossum* was exemplified at the auction rooms this week, when Messrs. Sander & Co. obtained for a supposed hybrid, *O. crispum* × *luteopurpureum*, the sum of 105 guineas. The flowers of this plant were three inches in diameter, yellow, with blotches of chestnut brown.

**ONCIDIUM SPLENDIDUM** is a most useful winter-flowering Orchid. It requires warm greenhouse treatment and plenty of sunlight to develop fully its broad pseudo-bulbs, thick, fleshy leaves and tall spikes of yellow and brown flowers. These last are in fine condition now. It is difficult to understand those botanists who insist on calling this plant a variety of *O. tigrinum*, also flowering with us now. There is some resemblance in the size and color of the flowers of the two, but in the form of the labellum, the size of the basal lobes, as well as in the character of the spike, there is a wide difference. Then, again, *O. tigrinum* is deliciously fragrant, while *O. splendidum* has no odor. In the characters of pseudo-bulb and leaf there is a marked difference between these two plants, *O. tigrinum* having thick, smooth pseudo-bulbs, with two, three or four comparatively thin, curved, shining green, acuminate leaves, while in *O. splendidum* the pseudo-bulbs are flattish, rugose, and each bears only one oblong, blunt leaf, which is very thick, erect, and becomes purplish with age. Another important difference is that while *O. tigrinum* is easy to grow and keep in health for an indefinite time *O. splendidum* soon wears out under artificial treatment. These differences have been spoken of as "no more than what might have been brought about by local environment," an argument which might be used with much greater reason against many species and even some genera.

**BULBOPHYLLUM DAYANUM.**—Although this plant has been in cultivation since 1865, when it was named by Reichenbach in compliment to that eminent amateur Orchid grower, the late Mr. John Day, it is rarely flowered. A plant of it was shown in flower last week from the collection of the Hon. Walter Rothschild, Tring, where *Bulbophyllums* of all kinds are grown exceptionally well. *B. Dayanum* belongs to the small, compact-growing set, the pseudo-bulbs being crowded on thin creeping rhizomes, roundish, smooth, about an inch in diameter and of a dark red-purple color.

The leaves are three to four inches long, elliptic, green above, reddish beneath. The flowers are clustered and borne singly on short petioles; they are each an inch in diameter, the sepals broadly ovate, green, with purple streaks and fringed with long hairs; the petals smaller, colored red and yellow; the lip trigonous, green, with ridges of blood-red on the disk. It is a native of Tenasserim. There is a figure of it in *The Botanical Magazine*, t. 6119. An example of it has been in the Kew collection many years.

**ORCHID FARMING.**—An interesting paper is published in the Bulletin of the Botanical Department, Jamaica, for November, 1896, by Mr. R. Thomson, formerly Superintendent of the Botanical Department, Jamaica, recommending the naturalization of *Odontoglossum crispum* in the Blue Mountains of Jamaica, with the view of supplying the now enormous demand for this Orchid which, through various causes, is being rapidly exterminated from its home in the Colombian Andes. He proposes that groups or colonies of this Orchid should be established at intervals of a mile or so in the forest where they would seed, and "in the course of ten years scores of thousands of plants would be naturalized and fit for export annually." Mr. Thomson points out that about twenty-five per cent of the plants of this *Odontoglossum* exported from Colombia perish in transit to Europe, owing to the long distance from the collecting grounds to the port, a difficulty which would not be experienced in Jamaica. *O. crispum* is certainly by far the most popular of all garden Orchids. Mr. Thomson estimates the annual export of plants to Europe at not less than 100,000 for the last twenty years. He also says that "this year several great Orchid growers have requisitioned 250,000 plants." Fifteen years ago this Orchid was obtainable in the Pacho district, the home of the best forms, for a couple of dollars a hundred, when a peon collected as many as 200 a day. Now he collects about ten a day, and consequently the price to him has increased tenfold. In a state of nature, seeds of this Orchid are produced in vast abundance, and being very light and chaff-like are disseminated by millions. Mr. Thomson's suggestion is well worthy of consideration, not only in relation to *Odontoglossum crispum*, but also to many Orchids which are in great demand in Europe, but which are difficult to get from their native countries. With few exceptions, the multiplication of Orchids by the usual methods of seeds, cuttings or division is practically impossible. It would, therefore, be worth while to apply the experiment recommended by Mr. Thomson in the case of various Orchids and in different countries.\* At present we do not even know whether varieties of Orchids come true from seeds. Such rarities as *O. crispum*, var. *Stevensi*, *O. Pescatorei Veitchii*, *Cypripedium Stonei platytanum* and *C. Fairreanum* would be excellent plants to start with.

### Notes on Cherries.

**ABOUT** ten years ago several varieties of Cherries, chiefly European importations, were received from Professor J. L. Budd, of Ames, Iowa, and planted on the experimental grounds here. Most of the trees have fruited for a number of years, but very little has been published concerning their behavior in this climate. The soil on which they were grown is a heavy sandy loam underlaid with gravel.

As would naturally be supposed, the trees are all perfectly hardy, and have made a good growth. Of nineteen varieties which fruited during the past season only a few possess any superiority to our older cultivated varieties which would warrant a more extended trial. The greater portion of them are in no way better than the old Early Richmond. The following notes were taken during the fruiting season, and are given here for the benefit of those who may wish to plant some of these varieties.

Brusseler Braune makes a larger tree than Early Richmond, and has shown itself to be a heavy bearer. The fruit is large and nearly black when fully ripe; stem two inches long; flesh

Fig. 8—View in a Grove of California White Oaks, *Quercus lobata*, near Visalia, California.—See page 54.

firm, juicy and of fine quality; juice highly colored. It ripens about June 25th in this latitude, and is one of the most promising varieties in the list. Montmorency probably stands next, with its large, bright red, showy fruit. In productiveness it equals the Early Richmond, but ripens ten days to two weeks later.

Lutorka is a large, bright red cherry with a deep suture, with firm flesh and of good quality, ripening about June 10th. This variety has received favorable comments from growers in the east as promising. So far, with us, it has been a very shy bearer; otherwise it would be recommended for general planting. Griotte du Nord is a good tree, with fine foliage. The fruit is large, almost black when fully ripe; stem two inches in length. It resembles the Brusseler Braune in general appearance, but ripens a little earlier.

Dye House has been spoken of very highly in some localities, but with us it is only medium; no better than many others. French Morello is a large, dark red cherry of good quality and quite productive, ripening about June 25th. Montmorency Extraordinary is of medium size, bright red, good quality, short-stemmed, and ripening June 10th. Frühe Morello is a large, bright red fruit, of fine quality, short-stemmed, quite productive, and ripening June 8th. Späte Morello is a good bearer; fruit medium in size, dark in color when fully ripe. The skin is tough, making it a good shipping variety; ripens June 25th. Wragg makes a low-spreading tree, with fruit of medium size, dark red and of very good quality when fully ripe; ripens June 25th. Weirs No. 2, inferior and not recommended for this locality. Bessarabian would be a fine variety if it were more productive, but thus far it has produced very sparingly. The fruit is large, dark red and of good quality, and ripens about June 20th. Cerise de Osthheim is a round-topped tree, the branches somewhat pendulous in growth. It seems to be one of the best varieties of its class that we have fruited. The fruit is medium in size, of a dark color when fully ripe; flesh firm and tender, juicy and rich, and the tree yields a heavy crop every year. Frauendorfer is a strong-growing tree, with large dark red fruit, tender and juicy. As yet it has not been prolific enough to warrant us in recommending it for general cultivation. Carnation is a sweet cherry of great promise. The fruit is very large, bright red, rich and meaty. It ripens about June 8th, and is a most excellent variety for family use.

### Greenhouse Notes.

WHAT may be called the busy greenhouse season is now at hand. In the Palm-house the principal work is cleaning and sponging, preparatory to repotting, and in the Orchid-house potting is the work in order, while in the propagating-house the benches will soon be taxed to their utmost capacity. We usually commence propagating with Crotons, Dracænas and similar greenhouse subjects to give them as long a season as possible. The main trouble in the cultivation of Dracænas is what is commonly known as club-root. This makes its appearance very quickly if the plants are allowed to become stunted in growth, either from the soil becoming sour through an oversupply of water or insufficient drainage, or from excessive dryness. There is no cure for this, so far as I know. When it appears, cuttings should be made of the top and stem and the old diseased root be destroyed.

Rose cuttings should be struck before the sun's rays become too strong, as it is then possible to supply a genial bottom-heat and at the same time keep the atmosphere of the house comparatively cool. The sand must be fresh and clean and kept well moistened until the cuttings have rooted. We prefer thumb-pots for the first potting; the smaller the pot the less is the danger from overwatering before the roots have sufficient strength to use the moisture. A light sandy soil is best for this potting, but for subsequent pottings it should be moderately enriched with dried and finely sifted cow-manure that has been well frozen.

Carnations may be struck, either in a hot-bed or under comparatively cool treatment. We prefer the latter system, for, though it takes longer, better and healthier plants are produced. The hot-bed method rushes the plants into weakly growth from which it takes them considerable time to recover, even if they are removed to cooler quarters after being struck. The first of March is quite soon enough to put in cuttings of bedding plants such as Coleus, Alternanthera, Strobilanthes, etc., unless the stock of any of these is short or extra-large plants are desired. By allowing the stock-plants all the possible light and air now, stout, firm growth will be promoted and the striking will be much easier when the time arrives for it.

Cyclamens still continue to bloom freely. This season,

instead of using leaf-mold and sand as heretofore, for the last shift in September, we substituted a liberal addition of turfy loam for one lot. The experiment was altogether satisfactory, and we mean to grow all in this way in the future. The growth is more compact, the leaves firmer in texture, the flowers stronger and more durable, while the quantity is slightly increased. The young plants from seed sown in October are now ready for a second handling. Frequent shiftings while the plants are young promote compact growth and also prevent the leaf-mold becoming sour or cloggy. As it is hard to regulate the moisture in soil of this nature, the house in which they are grown is run at a night temperature of fifty degrees, a rise of fifteen degrees being allowed by sun-heat. A light sprinkling is given two or three times daily during bright weather. The old plants intended for seeding purposes are kept apart from the others on a shelf well up to the light, and these are labeled in distinct colors so they shall not be mixed. We usually do some hand pollination with a view to strengthening some of the weaker growers or to impart brightness of color to those lacking in that respect. As there is danger from damping during the seeding period an oversupply of moisture must be carefully guarded against.

Cinerarias are now well established in their flowering-pots, and free growth is promoted by frequent applications of weak liquid-manure. The points of the leading shoots were removed before the flower-buds began to show. We consider this operation of considerable importance, as it induces branching and gives a larger and better-balanced plant.

Last year we set plants of Calla out in the garden after they had finished flowering, about the beginning of June, and lifted them again in the fall. They commenced to flower rather earlier than usual under the drying-off system, but otherwise there was no marked advantage. It is a mistake to grow them under too high a temperature, and forty-five degrees by night is quite high enough; at this temperature the flowers will be much stronger and more durable than if grown in more heat, while the plants are less subject to the ravages of insect pests, such as greenfly and thrips. Frequent syringing will help to keep these in check, but if the latter pest gets a footing the leaves must be sponged with a moderately strong solution of whale-oil soap or other insecticide. Smock will destroy the fly, but must not be given too strong; rather make the applications more frequently. These plants are strong feeders, and stand a liberal supply of liquid-manure.

Ferns grown from spores sown in November are now ready for pricking over, and will make nice, useful, little plants for filling small vases by May. Another sowing should be made during the early spring to come in later, as the first lot grow too large for the smallest vases. We use varieties of the Pteris family principally, these being the most durable, but a few Adiantums are also useful. The old plants of the latter should be potted on before the young growth is too far advanced, and Davallias and other rhizomatous sorts should be divided if it is desired to increase the stock by this means.

Tarrytown, N. Y.

William Scott.

### Flowers in January.

GREENHOUSE plants toward the end of January have a look of vigor due to the increasing sunlight. The change in the plants is mostly shown in the production of shoots and leaves rather than of flowers. There are not many blossoms except of bulbous plants which thrive in the dark, short mid-winter days, and after about ten weeks of abundant flowering these will continue for, perhaps, a fortnight longer, when a month or two is devoted to the ripening of their bulbs preparatory to a long rest. I still have one much belated flower of *Dahlia imperialis*, a noble species, whose natural blooming time is the end of November. The plant is a fine greenhouse shrub, with the drawback of too tall growth. Its habit is to run up ten or twelve feet, and then form a head of foliage from every axil of which the flower-stalks shoot, each bearing from one to three bluish-white flowers; in form these are more like a Lily than a Dahlia, and from four to six inches across. An Italian firm of seed growers state that they have some seminal varieties of this species which are of earlier bloom and dwarfer growth; if their hopes are realized we shall some time have a race of Lily Dahlias for garden decoration. The ordinary kinds are subject to red spider when grown under glass, but this is quite free from the pest.

Lachenalias are mostly past. *L. Nelsoni*, a fine hybrid with a stem a foot high thickly hung with waxy deep yellow bells an inch and a half long, is now in full beauty. This is one of the best in my collection, but it sometimes bears green-yellow flowers. *L. isopetala*, which commonly is the latest to flower, is just beginning to blossom. While not showy, it is quite

pretty with its thickly clustered violet-colored buds and small straw-colored flowers. The procession always begins with *L. quadricolor*, known also as *versicolor* and as *superba*, followed closely by *L. pendula*, the largest and finest of all. About twenty kinds are obtainable, and all, I think, are worth growing.

*Oxalis* of many kinds continue to flower. *O. Bowiei*, the largest and best species, has been blooming steadily since October, as has *O. cerima*, which I should rank next to *Bowiei*. This species has been introduced into Malta and has become a nuisance in cultivated land, and I read only yesterday that our little American *O. violacea* has become an intolerable pest in some parts of Ceylon. Many of the varieties of *O. purpurea* are now flowering. The flowers are purple, lilac, rose, pink, flesh-colored or white, and are frequently two and a half inches in diameter, but there is only one to the stalk. *O. gigantea* of some catalogues is really *O. purpurea laxula*. The stalks of the leaves and flowers are bright crimson, adding much to the beauty of the plant. Of the flabellate-leaved kinds, *O. crispa*, with its deep yellow flowers, and *O. leperina*, with white ones, are still beautiful, while *O. spectabilis* is just beginning to throw its clusters of dark crimson blossoms up through the masses of deep green leaves.

*Hemerocallis fulva* is not often seen in winter. Under glass it has a more refined look than out-of-doors, but it does not, of course, warrant the space it occupies. I took in a pot of *H. fulva* two years ago to hasten it for crossing with *H. flava*. I succeeded, and forgot to throw it out again. It has just finished flowering.

*Ferraria strata* is beginning to open its curious and attractive flowers; so are *Veltheimia viridifolia* and *Dendrobium nobile*, and *Phajus grandifolius* is pushing up its stout flower-stalks. One of the most uncommon plants now in bloom is *Ceratophylla triloba*, a perennial plant from south Africa. It grows in the greenhouse to a height of about two feet and produces spikes of hanging and thickly set flowers, shaped somewhat like those of the Foxglove, but with the lowest lobe prolonged in a triangular or trowel-like shape. These are produced at various seasons; they are pink, marked with darker lines, and are about three inches long. I have tried the plant in the open ground in summer, but it grew so rampantly that fall approached before it was ready to blossom. *Tritonias* are just beginning to flower. Nankin is always the first seedling variety of *T. crocata*; this fine large flower is of a creamy white color, tinged on the edges with red. *Babianias* have little beauty, *Sparaxis* produce but few flowers, *Ixias* are hard to manage under glass, but *Tritonias* are the most satisfactory of the smaller Cape bulbs for greenhouse use.

In speaking of January flowers, the hybrid *Streptocarpus* must not be forgotten, though they are always in bloom. So far I have raised no seedlings which do not fall under one of two descriptions: white, with lines of purple, rose or crimson; mauve, with lines or blotches of violet. This is no great range of color, but they are more distinct than many of the hybrid *Cypripediums* which have received varietal names.

Canton, Mass.

W. E. Endicott.

### Sowing Flower Seeds.

IT is not always easy to discover the real cause when there is failure in seed-sowing, and the seedsmen are often blamed when really the cultivator is at fault. Special conditions are necessary for successful germination, and must be maintained during the period intervening from sowing-time. The first thing to consider is whether the seeds are of tropical, semi-tropical or hardy plants, and in this our seedsmen should be able to help us. Seeds of tropical plants require a temperature of at least eighty degrees, Fahrenheit, and moist surroundings. For semi-tropical plants sixty degrees is suitable. A lower temperature will answer for many hardy plants; but the degree of hardiness varies as does the vegetating point, and some grow at a temperature scarcely above freezing. When Siberian Squills and Glory of the Snow break through the ground in early spring, thousands of seedlings appear almost at the same time. The effect of temperature on germination is well illustrated by two of our worst weeds, Chickweed, a native of temperate regions, and Purslane, a tropical plant. We have Chickweed from the opening of spring until the middle of June, when Purslane begins to appear and is our worst pest. After the first frost kills the Purslane, Chickweed again becomes troublesome. The shadiest and coolest place must be selected for *Cinerarias*, *Calceolarias* and *Primulas* if these are sown in summer-time, and then only moderate success may follow, whereas, if the sowing is done in February or March, or in September or October, the result is likely to be

altogether satisfactory, because the conditions of heat and moisture can then be made favorable to their nature.

Whether we start our seeds in a cold frame, a hot-bed or a greenhouse, depends on the facilities at hand. A hot-bed may be started now, but a cold frame cannot be brought into successful use until the beginning of April. If I had a greenhouse I would commence seed-sowing now, for, in addition to all tender plants raised for summer display, many hardy annuals and some perennials will germinate as well indoors and have better attention, with the result of earlier flowers. Some hardy perennials require a long time to germinate, and often a whole year will elapse before the seeds come up. Whenever this happens we know from experience that it is better to sow in autumn, and winter the seed boxes in cold frames. Seeds that are slow in vegetating should be sown as soon as they are ripe, or during the autumn. It is probable none will germinate until spring-time. If such seeds were held for spring sowing, few, if any, would come up until autumn, and some would remain dormant for another year. This has happened with *Barberries*, *Clematis*, *Rhodotypos kerrioides*, *Pæonies*, *Hellebores* and *Dictamnus*.

A light, sifted soil, with charcoal dust added, is suitable for nearly all seeds, certainly of all terrestrial plants. Shallow boxes are preferable. We use the shiftings for drainage, and then fill up the boxes to within half an inch of the top with the prepared soil, which is made moderately firm and smooth. Drills are marked out with the edge of a label, and the depth of the drills is varied according to the size of the seeds. Very fine seeds need no drill and may be scattered along the surface. A shaking will generally sufficiently cover them, and the surface should again be pressed smooth. With the exception of very coarse seeds, I do not practice overhead watering, preferring the subirrigation plan of immersing the boxes to the edge and letting in the water from below. Less frequent wetting is thus required and most seedlings will be up before a second application is necessary. There are several ways of disposing of the seed boxes until germination takes place. When space has been limited I have put the boxes away in tiers, so arranged that the bottom of one tier did not rest upon the top of the other—that is, set up so that air could freely pass over the soil. The seeds germinated as well as when the boxes have been spread over more space. By this plan only the top box needs shading, and less watering is required. As soon as germination takes place I expose the young plants to light and air. At this stage they require very careful watering, otherwise they would all quickly damp off. The seedlings should be transplanted as soon as they are large enough to handle.

Among the most useful plants for a summer's display are those which furnish cut flowers. We like to have these as forward as possible. Among these we group Stocks, Asters, *Coreopsis Drummondii*, *Phlox Drummondii*, *Angelonia grandiflora*, *Salvia Blue Beard*, *Indian Pinks*, *Gaillardias*, *Senecio Jacobæa*, *Scabious*, *Rocket Larkspurs*, *Zinnias*, *Verbenas*, *Chrysanthemum carinatum*, var. *Burridgeanum*, and small Sunflowers. All these we shall sow at once in intermediate temperature. Another group, also more or less tender, will include plants useful for the borders or for bedding, such as *Antirrhinums*, *Pentstemons*, *Petunias*, *Begonia semperflorens* *Vernon*, *Salvia splendens*, *Browallias*, *Celosias*, *Balsams* and *Poppies*. If time and space permit it we may sow some hardy perennials in a cool greenhouse. We shall, however, be likely only to try a few novelties or rarities in this way and leave the bulk of the hardy varieties for the cold frame. A good selection of perennials should include some of the fine hybrid *Delphiniums*, particularly *D. formosum*, var. *cœlestinum*, *Iris Kämpferi*, *Oriental Poppies*, *Campanula grandiflora*, hybrid *Phlox*, *Pæonies* (these are slow of germination), *Mertensia Virginica*, *Lupinus polyphyllus*, *Trollius Europæus* and *T. Asiaticus*, *Pyrethrum rosea*, *Heuchera sanguinea*, *Dictamnus Fraxinella*, *Sweet Williams*, *Lobelia cardinalis* and some of the new hybrids of *L. fulgens*, *Hollyhocks*, *Foxgloves*, *Asphodels*, perennial *Sunflowers*, species of *Asters*, *Alyssum saxatile*, *Thermopsis Caroliniana*, *Baptisia australis*, *Hemerocallis Thunbergii* and *Coreopsis grandiflora*.

Wellesley, Mass.

T. D. Hatfield.

### Notes from Baden-Baden.

**Iris Histrio.**—Owing to the mildness of the season this *Iris* opened its first flowers by the end of November, and buds are still coming on, prolonging the flowering time to the end of January. It is a native of Mount Lebanon and belongs to the *reticulata* group, having the largest flowers of this tribe. The body-color of the flowers is bright ultramarine, the three blades having only a colored rim; the middle parts are white,

with blotches of deep ultramarine and a yellow crest. Blue flowers are rare about this time of year, and its fresh color makes it very welcome. It is not quite hardy, and must be either potted or cultivated in a frame, but it well deserves such extra care. Its near ally, *I. histrioides*, is quite hardy, but it does not make its appearance before the middle or end of February, and its flowers are smaller.

A new *Colchicum* from Persia is showing bud and will be out as soon as we get a few bright days. Although its white and pink flowers are small they are borne in great numbers, and on account of their earliness this *Colchicum* will be a welcome addition to spring-flowering bulbous plants. I have been fortunate in securing a small importation of the rare and beautiful *Scilla Messeniaca*, which is to flower in March and on which I will report later.

Baden-Baden.

Max Leichtlin.

### Evergreens in Winter.

To the Editor of GARDEN AND FOREST:

Sir,—Evergreens and shrubs that retain their berries until spring are now the leading attraction of the winter garden. The conifers used to form shrubberies for effect in the dark season should be those that retain a healthy appearance of their foliage throughout the winter. The foliage of many evergreens burns and browns under the varying conditions of sun and storm, freezing and thawing, to which they are subjected at this trying time. For a number of years I have taken note of many Pines, Spruces, Retinosporas, Arbor Vitæ and Hemlocks, and I have been much struck by the variety of appearance the different species and varieties assume at this season. In this climate the Arbor Vitæ and Retinosporas give less satisfaction than do some other conifers, as they look dull and rusty even in mild winters, and are only beautiful during the season of growth. Such conifers are not as well adapted for winter gardens as the Spruces, Hemlocks and Pines. Strangely enough our native Pines do not compare favorably with those of foreign origin in this regard. In my little pinetum it is the American Pines whose foliage discolors in winter. The common White Pine, *Pinus Strobus*, for instance, has a way of folding its needles together as if it were preparing for a long winter's sleep, and all its foliage assumes a dull olive-gray tint, in striking contrast to the wide-awake aspect and sprightly green of some of its foreign neighbors. *Pinus excelsa*, the Lofty Bhotan Pine, one of the most beautiful of its class, is very effective in the winter landscape here, and is almost as bright a green now as in the summer. The same may be said of *P. Thunbergii*, from Japan, and of the Swiss Stone Pine, the Austrian Pine and others. Our native Cedars, *Juniperus Virginiana*, now have a dark, dingy appearance, which is particularly noticeable when the ground is covered with snow. Some very young trees of this species turn a deep purplish green. In very mild winters like the present the Irish Junipers retain their fresh color throughout the season, but they winter-kill badly from the excessive freezing and thawing of cold changeable weather.

Perhaps the most satisfactory of the conifers in our collection for winter color is the Douglas Spruce, *Pseudotsuga taxifolia*. It certainly is not surpassed by any other known to me for the clear, bright green of its foliage at this time. As grown here it is a compact tree, feathering out quite to the turf with graceful, downward sweep. Its foliage has a peculiar softness to the touch, and it succeeds best on exposed hillsides, where it does not discolor in the severest winter. The Spruces, too, as particularly desirable for winter effects are the Blue Spruce, *Picea pungens*, and a glaucous form of White Spruce, sold under the name of *A. cœrulea*. A variety of the Norway Spruce known as *Conica* has dark foliage and retains its color well, but is not so graceful in habit of growth as some other Spruces.

Hemlocks have a beauty all their own, and are never as charming as when their graceful branches are slightly bent under a light fall of snow. When Bittersweet vines are allowed to clamber at will over a clump of young Hemlocks the effect of the latter is much enhanced by the bright berries that mingle with their airy foliage. *Cupressus Lawsoniana* deserves mention as one of the most cheerful of evergreens as seen here in winter. It is hardy with us and is planted on the crest of a hill, a situation which suits it better than any other.

It may be that in other localities trees which grow dingy here hold their fresh color in the winter. I am only giving my personal observations.

Rose Brake, W. Va.

Danske Dandridge.

## Meetings of Societies.

### Western New York Horticultural Society.

THE forty-first annual meeting of this society, which stands in the very front rank of organizations devoted to fruit-growing, was, as it usually is, largely attended, and several of the papers were notably instructive. It is said that the meeting did not move with the vim and snap which has characterized the proceedings of this body in years past, and those who have attended former gatherings can hardly imagine a dull hour at one of them. But fruit growers who are cheerful this year are made of sturdy stuff.

#### ADDRESS OF PRESIDENT BARRY.

After an historical sketch of some of the earlier societies in the country, Mr. Barry spoke of the exceptional weather and the exceptional crops of last season. In the first place, the winter was long and severe, remarkable for periods of extreme cold and heavy falls of snow. In January, while the ground was bare, a period of extreme cold came, in which large orchards of Duchess Pears suffered injury, many of the trees being found dead. Of other varieties of Pears the Anjous suffered least. President Barry does not know whether this injury to the trees will be permanent, but the question of the comparative hardness of varieties is one which certainly is worth investigating. Snow lay on the ground till late in March and kept out the frost, and on the first of April nurserymen began to lift and pack trees. There was no delay from frost as usual, but there came a sudden and intense heat which prevailed during the middle of the month, with the thermometer in the eighties for several days. This made the packing and the shipping season the most hurried that has ever been known here, for by the first of May every tree was in full leaf, and the season for planting was practically passed. After this abnormal beginning a drought succeeded, with little rain, till the 20th of July, and this resulted in much loss to newly planted trees. The summer was hot, and, although comparatively dry, plants of all kinds which survived the early drought made a growth which surprised every one. For several years in western New York the orchards had produced but light crops, so that the trees were in a condition to yield heavily, and the apple crop was enormous. Every tree which was of bearing age was filled with handsome fruit. The result was surprising and discouraging, since only a small proportion of the fruit brought remunerative prices, most of it being taken to cider-mills or evaporating-houses, or utilized in other ways which gave small returns. Excessive quantities were exported to Europe, and instead of using extra care in selection on account of the exceptional crop, shippers hurried to pack without proper care in selecting, so that in many cases they received hardly enough to pay for their barrels. In this way the crop at home and abroad was practically lost.

President Barry advises that storage houses be provided where fruit can be kept till the time arrives when it can be advantageously sold. He added, as a practical point, that among the varieties which growers in the neighborhood of Rochester had an opportunity to test, Jonathan heads the list as a handsome, delicious and profitable apple. Its size, shape, color, flavor and shipping qualities are all that can be desired, and it is strange that a variety possessing so many desirable characteristics should not have long ago received greater attention. An orchard of Jonathan apples is one of the most beautiful spectacles in nature, the tree being naturally graceful, the branches willowy, and the dark red apples against the bright foliage present a picture which never fails to excite admiration. The President also had a good word for the new plums raised by Luther Burbank, of California. He advised fruit growers to enlarge their spheres of work and to cultivate fruits for different seasons of the year so as to give employment to a regular force of laborers, who, on account of their proficiency, would become indispensable on the fruit farms. Crops should be anticipated and markets provided by the fruit grower, just as the manufacturer seeks and secures sales for his goods. Only by alertness in marketing, as well as care in growing—that is, by conducting fruit-growing on business principles the year through—can success be assured. Under existing conditions it will never answer to leave anything to chance.

#### NEW FACTS ABOUT THE CODLING MOTH.

Professor M. V. Slingerland, in speaking of recent work among Insect Foes of the Horticulturist, urged all fruit growers to coöperate with the stations, so that practical

horticulturists and economic entomologists could mutually aid each other in studying the habits of injurious insects. After a brief sketch of economical entomology in this country, which began practically with Dr. Harris' famous treatise, published in 1841, science has made great advances. But there are many things to learn. Even when we have discovered the proper remedies, there is sometimes uncertainty as to when and how they should be applied. Besides this, there is more than one fraudulent remedy on the market, as, for example, the inoculation humbug, which claims to render a tree safe from the attacks of many insects by a compound to be inserted in a hole bored into its trunk. Last year thousands of pounds of the American Soil Renewer and Insecticide were sold in Minnesota under a guarantee that it would kill every chinch bug on a field where it was sown, and so impregnate the soil that the insect would never again invade it. Chemists showed that the compound consisted of salt, land plaster and a little hellebore. The experiment stations have shown, too, that a patent Potato Bug Exterminator is entirely worthless, and that some really good insecticides are badly adulterated, so that the practical fruit grower must be alert to keep up with the latest investigations. We are learning something about it every day. For example, the arsenate of lead brought out by the Gypsy Moth Commission in Massachusetts as Gypsine is a promising remedy, so is an arsenite of copper known as Shields' Green and the arsenite of lead. Whale-oil soap seems to be destined to come into general use as an effective remedy for the dreaded San José scale, and with the improved machinery worked by horse power or steam engines there is every promise that it will be possible to wage more successful war against the insect enemies of crops in the future than has ever been waged in the past. Those who know most about insects and their methods of life will be most successful in destroying, and we have much to learn of the habits of our most common ones. We do not know, for example, how long the June bug lives as a white grub, nor the click beetle as a wireworm. We do not know where or when the click beetle lays her eggs, and no one has yet reared a June bug or a click beetle from the egg to the adult insect. Mr. Slingerland has been making a special study of the apple worm, or codling moth, and he seems to have thrown light upon some portion of the life and habits of this insect which have hitherto been obscure. It has been known that a spraying of Paris green, if applied to Apple-trees just after the blossoms fall, will kill the caterpillars; but the explanation as to how this poison killed the worm has been obscure, since no one seems to have made any definite observation of the eggs and the newly hatched caterpillars. The text-books say that "the moth lays its eggs singly in the maturing blossoms of the apple just as the petals fall. As soon as the caterpillar hatches it burrows into the apple." All writers tell glibly where this egg is laid, but only one, so far as Mr. Slingerland knows, has ever seen the egg, and this is remarkable, since the literature of the codling moth began 170 years ago and is as voluminous as that of any other injurious insect. Nevertheless, a bulletin of the Oregon Experiment Station published in 1893 contains the first and only picture of the egg yet published. The author of this bulletin, Mr. Washburn, thought that these eggs were laid anywhere it happened on the skin of the fruit, and they were laid somewhat later than was supposed. Later writers have overlooked these important observations, and Mr. Washburn himself did not watch the young caterpillar after emerging from the egg, and thus left it uncertain as to how he gets his deadly dose of Paris green. Mr. Slingerland has found that the greater part of the eggs are not laid until about a week after the blossoms have fallen and when the apples are as big as hickory nuts. The calyx lobes on the young fruit are by this time drawn tightly together, so that it would be a hard matter for the moth to insert her egg in the cup. In fact, the ovipositor is only adapted to laying eggs on the surface of the fruit. These round, thin, scale-like, translucent eggs, not quite as big as a pin-head, are glued to the apple skin, with little choice as to their location on the fruit. It is a week before they hatch, and therefore it is ten days or two weeks after the blossoms fall before the caterpillar begins operations. Now, if the usual advice for spraying has been followed, the first spraying is made a week before the eggs are laid, and the second some days before the worms appear. How then does the poison kill the worm? A study of the growing fruit shows that when the petals fall the remaining calyx lobes are broadly spread out like a saucer and many minute particles of Paris green are caught in it, but as two weeks must intervene before the little caterpillar begins to eat, much of the poison would be washed out by rain and the first spraying would be

useless. Nature prevents this, however, by tightening up the calyx lobes at their tips as the apple grows, so that within a week after the blossoms fall the cup has its deadly dose protected by a cover formed of these converging lobes. How then does the worm, when he begins to eat a week or more later, get hold of the poison? Professor Slingerland watched one of the little creatures as he came out of his egg and wandered over the surface of the apple for two or three hours, eating nothing, but simply exploring until it had worked its little body through between two of these calyx lobes and disappeared within the cup. Future field work confirmed this observation and showed that the worms fed about the cup for a day or more before they go deeper into the fruit. Apples were picked from a tree which had been sprayed just after the petals fell, and an analysis showed that there was arsenic in the covered cup of the calyx. As eight-tenths of the first brood of worms begin feeding in the manner described it is believed that this first spraying just after the blossoms have fallen is of the utmost importance and will kill more caterpillars than several later applications.

After detailing this bit of investigation and discovery, Professor Slingerland had something to say about the Peach-borer, showing that washes were comparative failures, and that dendrolene, though it gave some promise as a preventive, should be carefully used. He hopes that there will be some easier method found of combating the borer than by digging it out, but as yet this is the surest and most practicable remedy to be commended. A thorough digging in the latter part of June, when the worms are three-fourths grown, would be more effective than a spring and fall examination together.

### Recent Publications.

*Vegetable Gardening.* By Samuel B. Green, Professor of Agriculture in the University of Minnesota. Webb Publishing Co., St. Paul.

This is a compact little manual of 225 pages which was prepared originally for use in the School of Agriculture connected with the University of Minnesota, and it treats of the growing of vegetables both for home use and for market. It was written for the latitude of southern Minnesota, but a little judgment will enable any one to adapt its directions to locations farther south and north. About half the book is taken up with the usual description of the various plants cultivated in kitchen gardens, together with good instructions for raising them. Like most other manuals, it could be improved by the statement of some general principles as the basis of special treatment, so that the cultural directions would have rather less of the wooden "rule of thumb" quality. A handbook would have more vitality and its teachings would impress themselves more strongly upon students if it contained such data, with the deductions from them as were presented, for example, in an article on Tomatoes, by Professor Tracy, in the last volume of this journal (vol. ix., p. 37). When an intelligent reader once apprehends that the constitution and habit of the Tomato clearly make it necessary to surround the plant constantly with certain conditions, he will never forget the details essential to its most profitable cultivation. Similar considerations drawn from a study of the development and character of other garden plants could be stated with great advantage, so as to offer readers for their contemplation and study some of the fundamental reasons for the different methods of treating different crops. Directions given to be memorized are easily forgotten; principles once learned are a possession forever.

The rules for cultural practice, however, are all trustworthy, and embody results of the latest studies at the Agricultural Experiment Stations and elsewhere. Besides these the book offers a good practical chapter on injurious insects and the methods of fighting them, some excellent notes on glass structures, a compact treatise on tillage and fertilizing, with tables of composition giving the amount of food elements required by different crops, the amount of these elements contained in various farm manures and commercial fertilizers, and much other useful matter written in a straightforward, sensible way. It is helpfully illustrated and has a fairly good index, but no table of contents.

## Notes.

Almeria grapes, from Spain, may still be had for twenty-five cents a pound, and four-pound baskets of Catawbas, from western New York, sell for the same sum. Handsome bunches of large Gros Colman grapes, from England, realize \$1.75 to \$2.00 a pound.

Only thirty barrels of cranberries reached this city during last week, while 64,000 barrels have come since the beginning of September, besides nearly 35,000 crates. Fancy grades from Cape Cod sell at wholesale for \$5.50, and the best from New Jersey for \$4.00 a barrel.

An important announcement by the MacMillan Company of this city is the publication of an encyclopedia of American Horticulture, in three volumes, dated 1900. Professor Bailey has undertaken the editorial oversight of the work, which will contain signed articles by specialists, arranged alphabetically, on all subjects relating to the cultivation of plants out-of-doors and under glass.

A correspondent of *The Gardeners' Chronicle* from Cape Town, South Africa, writes of a new yellow-spathed *Richardia*, which seems to be quite different from either *R. Elliottiana* or *R. Pentlandi*, and in many respects an improvement on both of them. The flowers are a very bright shade of yellow, the spathes are large and freely borne, the plant is bold, vigorous and stocky in habit, with broad leaves set on rather short petioles and regularly spotted over the entire surface of the blade. The plant is said to have been found in a place remote from the habitat of the yellow *Callas* already introduced.

Mr. John C. Lewis writes to *Forest Leaves* of a Buttonwood-tree which has grown from a sprout planted by William Rodman about the year 1745, some two miles from the Croydon Station of the Pennsylvania Railroad, at a place called Flushing, in Bucks County, Pennsylvania. It seems as vigorous as it was a century ago, and is still growing and bids fair to keep on growing through the twentieth century. At two feet from the ground the tree is twenty-nine feet six inches in girth, and at six feet from the ground it measures twenty-eight feet four inches. If there are larger trees than this east of the Rocky Mountains we should like to hear of them.

According to Mr. Fernow, in an address before the New Jersey Forestry Association, held at Trenton on the 5th of January, the people of New Jersey are sending out of that state at least twelve million dollars a year for lumber, two or three millions of which could be expended at home if the soil fit for these crops only was doing its duty. The greater portion of this area is almost totally unproductive, and its capacity for production is decreasing every year by recurring fires. One-third of it is in the northern or hilly part of the state, and the remainder in the sand-barrens so situated near places of active consumption that, with only indifferent care, it would yield a hundred million cubic feet of wood every year forever, or an annual stumpage value of at least one million dollars.

While only a moderate quantity of fresh vegetables arrived from Florida last week, there was no real scarcity. The crops north of Winter Haven are said to have been seriously injured by the recent frosts, but south of Tampa little damage was done. Some good lettuce has come from that state during the past ten days, with new beets, cabbage, eggplants and cauliflower. Many of the tomatoes have been of poor color, but good ones could be bought as low as twenty cents a pound. String-beans cost \$1.00 a half-peck, and peas \$1.00 to \$1.50. Escarolle, from New Orleans, costs ten cents a head, and that from France commands twenty to twenty-five cents. Okra and peppers come from Havana. Mushrooms continue plentiful at fifty cents a pound. Oyster-plant, turnips and other root crops are seen in large variety in local displays of vegetables.

Messrs. J. C. Houghton & Co., importers of apples in Liverpool, under date of January 30th, state that the favorable change of the previous week in prices for American apples in England has continued, and that there is a further general advance of one to two shillings a barrel. At that time Baldwins of choice quality, tightly packed and sound, sold at wholesale at from \$2.88 to \$4.08; Greenings, from \$2.46 to \$3.54; Northern Spies, \$2.52 to \$3.84, and Golden Russets, \$3.54 to \$5.04. "Slack" barrels realized from one to three shillings less than these rates. Other varieties now exported from this country are Ben Davis, Phoenix and Seek-no-further. Most of these apples were forwarded from Maine and Canada, and the few from New York are reported as having been in poor condition, Baldwins bringing but \$1.68 to \$3.00, and

Golden Russets \$3.36 to \$3.48. In Liverpool alone 1,235,925 barrels of American apples were received this season up to January 28th as against 329,126 barrels for the corresponding period a year ago.

Dr. John Marshall, of Philadelphia, who has his summer residence in Douglassville, Pennsylvania, came home after a short absence and found that a telegraph company had entered his grounds against the protests of the persons in charge, and cut down sixty or seventy trees and mutilated others, under the pretext of clearing a space for operating a telegraph line. Suit was brought in the Bucks County Court, and the men who committed the misdemeanor were sentenced to pay a fine of \$50.00 each, and in default of payment to be imprisoned for fifty days. An appeal was taken to the Superior Court of Pennsylvania, and we are glad to learn from *Forest Leaves* that the finding of the lower court was upheld. Beyond doubt, the owner of the trees has also the right under this decision to collect damages by civil suits in addition to the penalties imposed for the misdemeanor.

A correspondent to the London *Garden* says that Beet roots are often spoiled in cooking—that is, the most highly colored of them lose their beauty and the richest of them lose their flavor. In the first place they may be injured in gathering, for if the tops are cut off too close to the crown the root bleeds and this is a loss, and when sent to the kitchen in good condition the knife is too severely used in trimming off the ends before they are boiled. Besides this, they are often pricked with the fork to prove that they are sufficiently soft, and in this way the juice escapes into the water to the detriment of both flavor and color. Experienced cooks ought to know how long roots of a certain size require for their cooking, and they should never be interfered with from the time they are placed in the water until they are finally removed, when they should be peeled and prepared for the table.

The Trustees of the Veitch Memorial Fund have selected for decoration with their medal this year the following persons for distinguished service to horticulture: Mr. Norman C. Cookson, for long and successful experiments in hybridizing Orchids; Mr. Martin R. Smith, an eminent amateur, for raising choice varieties of Carnations, especially those in the Malmaison section, and others adapted for culture in the open border on account of their hardiness and beauty; Professor L. H. Bailey, of Cornell University, in recognition of the value of his lectures and writings as a help in placing the cultivation of plants on a scientific basis, and his efforts to promote the extension of horticultural education, and for his efforts to improve economic plants; M. Charles Naudin, of Antibes, for experiments which have advanced the theory and practice of hybridization, and for his success in introducing plants of great economic value; and Herr Max Leichtlin, of Baden-Baden, for his eminent services in introducing to horticulture a large number of interesting plants, and his sagacity and skill in their cultivation.

In writing to *The American Agriculturist* on Winter Work Against Insects, Professor J. B. Smith calls attention to the fact that many borers pass the winter as larvæ either in dead or dying twigs that remain on the trees or have fallen to the ground. All dead and dying wood should, therefore, be removed from orchards in the winter. Almost every dead or dying branch contains borers in some stage, and these should find their way to the brush-heap or into the stove before spring. If they are put on the brush-heap they should by no means be allowed to lie till the following summer, but ought to be burned before the first of April. Careful inspection at this season may show on Apple-trees which have been infested with plant lice many very small, shining, black, oval eggs close to the buds near the tips of the twigs. It is hard to kill these eggs, but if there is any trimming to be done these twigs may be cut off and burned before spring, and this will lessen the insects for next year. The egg belts of the tent caterpillar are more readily seen, and it pays certainly to cut them from medium-sized trees. Burning over infested land in winter will destroy the eggs of many grasshoppers and other insects which lay their eggs in the leafy tissue or on the stems of grass or reeds. Some insects which infest shade-trees, like the bagworm and the vapor moth, hibernate in the egg state. The bagworm can be easily cut off of the tree, especially the Arbor Vitæ, which is very subject to their injuries, while in cities and towns the egg masses of the vapor moth are found on fences, tree-boxes and any other place where a little shelter is afforded, and since each mass contains more than a hundred eggs, every one gathered and burned helps to limit the injury from caterpillars the next year.

## Agricultural Education.

AT one of the meetings of the Association of American Colleges and Experiment Stations a committee was appointed to examine Methods of Teaching Agriculture, and at the convention held in Washington last November the first report was submitted, and this has been published in full as circular No. 32 from the Office of Experiment Stations, in the Department of Agriculture. The first point to note is that a tabulation and summary of the replies sent from fifty agricultural colleges in response to letters of inquiry show that in this country, at least, there is nothing like a standard for instruction in agriculture. This does not mean simply that there are differences in the methods pursued in the various colleges which arise from different conditions; it means that there is no approach to anything like uniformity in courses of study or in the method of pursuing them. These colleges differ so widely in the topics taught, the order in which they are taken up, the time given to each one, and in the adjustment of the proportion of work in the class-room to practical work in the laboratory or on the farm, that it is almost impossible to compare one institution with another, or any of them, with a typical scheme for a regular course of three or four years. The committee, therefore, present their summary of data with the negative conclusion that they are not prepared to make any recommendation until more time has been taken to study and digest the facts presented. Indeed, the committee point out that the subject can hardly be discussed intelligently until there is a definite nomenclature in regard to the methods of agricultural teaching. The term "agricultural" is applied in a broad way not only to plant production, but to animal physiology, various special industries like dairying and sugar-making, to farm engineering and mechanics, to farm policy, including rural law, agricultural bookkeeping, etc. How the various subdivisions of the general subject are to be named the committee has not yet decided.

But, apart from the summary of data concerning our own colleges, there is an instructive series of observations upon the leading features of European institutions for agricul-

tural education. From this we find that the systematic efforts to educate people in agriculture in Europe are much more complex than ours, ranging from elementary instruction in the public schools up to post-graduate courses for those who have already taken the university degree. Beginning at the bottom, in many European countries there are (1) farmers' meetings like our own farmers' institutes, held for a day or so, at which there is a lecture or two and a conference, (2) short courses of lectures on special topics and on the general subject of agriculture, (3) evening schools for elementary instruction, (4) classes in agriculture in public or private primary schools, (5) courses in the normal schools to train agricultural teachers for primary schools, (6) courses in agriculture in the secondary public or private schools for general education, (7) schools of a higher grade managed by individuals or corporations and subsidized by the Government, (8) schools of the same grade, but exclusively under the Government control, (9) institutions for higher education in agriculture only, (10) the same kind of institutions, but connected with universities, and lastly, departments in the universities themselves. The special thing which arrests attention is the relatively large place given to the higher, or what we should call post-graduate education in agricultural science. Opportunities are offered for thorough training in any or all the sciences as applied to agriculture. The result of this is that the experiment stations, the schools of agriculture and the agricultural departments of the Government never lack for well-trained investigators or teachers, and, besides this, industries like sugar-making, which require scientific knowledge of a high order, can always find skilled laborers.

This is the most important feature in the whole system. Improvements in education usually begin in institutions of the higher grades; good primary schools, at least, only flourish in conjunction with the best institutions of the highest grade. It is the colleges where teachers are educated, and the higher institutions of learning which furnish an educated public opinion that make good schools of a lower grade possible, and until we have institutions where a body of workers can be trained to agricultural research our whole system, from the primary instruction in agricultural science upward, will be structurally weak. Of course, as it is stated in this report, some of our workers and teachers can get their training in foreign schools, but, while this is better than no training at all, they acquire a certain alien habit of thought which is a bar to their highest success at home. In our own country the conspicuous improvements in agriculture have been made by investigators in scientific fields. Our marked advance in fruit-culture has been due to the discovery of methods for checking the ravages of insects and of fungous diseases. Great improvements in dairying have been made by the chemists in our experiment stations, and a more rational system of animal feeding, which has added millions of dollars to the value of our stock-raising interests, has come from the same source. It would seem, therefore, that one of our first efforts should be to raise the standard of our colleges of agriculture so that they may turn out a class of men who have a broad grasp of the entire subject and are capable of making original investigations in the various sciences which are connected with the general subject; and before students are capable of making the most of a really high-grade course in agriculture they must, beyond question, have a thorough college training in the principles of the various sciences which underlie agriculture.

At the other extreme of the educational system, that is, in the primary schools, the first necessity is competent teachers. How children may receive elementary instruction in ordinary schools is well set forth in the account of a visit to a school in Belgium which has a well-equipped teacher. At the time of this visit the teacher was giving a lesson on the properties and uses of milk to a class of boys and girls about twelve years old. By means of elementary chemical experiments and skillful questions, with samples

of milk and cream in their presence, and much material illustrating the composition and uses of the fluid, the teacher gave to his class a simple and clear explanation of such matters relating to the uses of milk and its composition as they could reasonably be expected to understand, and as the different members of the class summed up what they had listened to it was apparent that they were well taught and that from that time forth their knowledge of milk was considerably wider than it would have been if they had never received the lesson. The teacher had hung charts about the walls of his school-room, pictures of agricultural implements and of different plants, and adjoining his school was a small garden in which many kinds of plants were growing, and where different methods of cultivation were tried for the instruction of pupils. The teacher was not a mere book man. His schoolroom was close by the rooms of the village agricultural society, where there were collections of seeds, charts with the composition of different fertilizers, and many other things which would be of interest in the discussions of the society, and which were available for use in the school. He was secretary of this society. He had aided the farmers in fitting up a coöperative dairy supplied with the most approved appliances for the creamery business, and by selecting, testing and purchasing fertilizers for them, and in many other ways. It was very plain that children trained under such circumstances would have a much broader outlook relating to agriculture, and be more inclined to avail themselves of advanced methods in agriculture than their fathers had been. Of course, it will be many years, if not generations, before we can hope for teachers of this sort in our country primary schools. Undoubtedly they are rare, too, in Europe, for only a beginning has been made in Germany, for example, to provide instruction in agriculture in normal schools.

We have no space to speak of the so-called secondary schools or schools of higher grade which are well provided with apparatus, collections of various sorts and material for illustration, nor of the institutions for higher agricultural education in many European countries. We can only say that it is not considered so important in these latter institutions that students shall learn definite things as that they shall acquire scientific methods of thought, and that the best educators are by no means certain that their systems cannot be largely improved. It will be a long time before we can have anything like systematic agricultural education either in common or high schools, and the most that we can hope is that by means of institutes and bulletins and the agricultural press the results of our experiment station work can be made directly useful to the farmers of the country, and that the character of this work can be made better and better. We cannot but feel, however, that an elementary knowledge of plant-growth and of other processes of nature will sometime be considered a natural part of the education of all boys and girls in the country, and this not simply because it will make them more successful farmers or fruit growers or truck raisers, but because as a matter of mental discipline it is an excellent schooling for anybody, helping to train the mind to habits of observation which can be used in any field of life, and giving a knowledge of facts and processes which will furnish pleasure and entertainment in all after life, even if it is not made directly profitable in work on the farm or the garden.

---

When a rock of any kind has lain for some time exposed to the weather, Nature finishes it in her own way. First, she takes wonderful pains about its forms, sculpturing it into exquisite variety of dent and dimple, and rounding or hollowing it into contours, which for fineness no human hand can follow; then she colors it; and every one of her touches of color, instead of being a powder mixed with oil, is a minute forest of living trees, glorious in strength and beauty and concealing wonders of structure.—*John Ruskin*.

### Notes on the Eastern American Spruces.

IN the new *Illustrated Flora of the Northern United States and Canada*, by Dr. N. L. Britton and Hon. Addison Brown, the Black and Red Spruces are maintained as distinct species, but there seems to be an unfortunate and, perhaps, accidental confusion in the description and a transposition of the figures. These two Spruces and the White Spruce comprise the only species recognized in eastern North America. In many of the modern writings, whenever the Red Spruce has been recognized at all, it has been merely mentioned as a variety of the Black Spruce, and the characters which distinguish it have sometimes been very vague. In the last edition of Gray's *Manual* the variety is better characterized than in any of the earlier editions.

With our present knowledge of these trees they appear as distinct species, although it is true that individuals apparently more or less intermediate in their superficial characters are not unusual.

The late Dr. George Lawson, of Halifax, Nova Scotia, in a little paper on the Canadian Spruces, read before the Royal Society of Canada in 1887, and apparently privately printed, probably did more than anybody else to call attention to the differences between the species. This paper has been reprinted by Professor Penhallow in the *Canadian Record of Science* for July, 1896. It appears that the Black Spruce, generally known as *Picea nigra*, was first described in the eighth edition of Miller's *Gardeners' Dictionary* (1768) as *Abies Mariana*, "the Black Spruce Fir of North America, with very small cones," and although the description is not very specific it may stand for the Black Spruce as now recognized.

In New England and New York, and in the adjoining states to the south and west, this tree is less abundant than the Red Spruce, although it may be found in most regions in which the latter grows. The Black Spruce, however, is generally found in bogs, on the colder boggy lands, around the shores of lakes, or wet places on hills and mountains; the Red Spruce, on the other hand, being found on the better-drained or warmer lands, whether in valleys or mountain slopes. In many localities the two species may be found intermixed or close side by side, and in some places the Black, Red and White Spruces may be found together, as, for instance, at Kineo, at Moosehead Lake, in Maine. Under favorable conditions the Black Spruce may become a tall slender tree, but in its best development it is smaller in size of tree, limb, twig and cone than the Red Spruce. Growing in open places it may be furnished with branches to the ground, but the branches are generally shorter, more slender, and therefore more drooping, than those of the Red Spruce. The branches are less regular in their growth—that is, they are not so uniformly graded in length from base to summit—which often gives the tree a straggly appearance and less of the regular conical aspect of the Red Spruce. As a rule they are much depressed instead of horizontal. The twigs are pubescent, with fine rusty brown hair or occasionally nearly glabrous, and are generally of a darker, duller red-brown color than those of the Red Spruce; and they are commonly more slender, the lateral ones becoming depressed or pendent.

The leaves generally seem shorter and less pointed than those of the Red Spruce, and they stand more erect or brush-like on the twigs. The distinctly dark blue-green or glaucous color of the foliage at once distinguishes it from the Red Spruce and gives it more of the aspect of the White Spruce, with which it has occasionally been confounded. On the tops of the trees or on the fruiting branches the leaves are often shorter and blunter than on the lower or non-fruiting branches.

In cold, wet, spongy, sphagnum bogs, where there is no real soil and the sphagnum sinks below water-level when trodden upon, the trees may be found bearing cones when less than three feet high and with stems less than an inch in diameter. Such diminutive trees may be many years old, scores of years old in fact, and are to be found in

their peculiar situations in Maine, New Brunswick and other parts of Canada, where they are often known as Water Spruce. On the firm ground adjoining such bogs the same species of tree grows to normal size.

The cones of the Black Spruce often seem clustered together in bunches, and they usually remain on the trees for several years after they are mature. Sometimes cones of the different seasons for the past twenty or thirty years may be found still persisting on the older trees, generally on the inner ends of the branches near the trunks. The mature cones, which are attached to the twigs by short, stout, recurved stalks, are generally ovate in form and have been well described as plum-shaped. When open they often appear nearly globular in outline. They average nearly an inch in length, but are often much less, and are occasionally as much as an inch and a half long. When young they are of a rosy purple or dark purplish color, changing with age until they are of a duller or more gray-brown color than those of the Red Spruce when both arrive at maturity and the cones open. The scales are rigid, are very thin and often pale-colored at the outer ends, which are sometimes quite narrow, and where they also often seem wrinkled, and the edges are quite distinctly uneven, eroded or notched. The cones do not open so freely as those of the Red Spruce and the scales do not allow the seeds to drop out easily or soon. The Black Spruce is the Muskeag Spruce, described and illustrated from a photograph, by Mr. H. B. Ayers, on pages 504 and 505 of the seventh volume of GARDEN AND FOREST.

The Red Spruce (now known as *Picea rubra*, and hitherto most frequently called a variety of *P. nigra* or *P. Mariana*, as it is now proposed to call *P. nigra*) is the principal Spruce timber-tree throughout the maritime provinces and eastern Canada, throughout Maine and the other New England states, New York and Pennsylvania, and extends farther south and west. Under most favorable conditions, as in the Adirondack forests in New York, it may attain a height of considerably over one hundred feet and a diameter of trunk of over three feet, although the average size as cut for timber is much less. A count of the annual rings shows the older trees to be more than two hundred and occasionally three or four hundred years old. Interesting tables of heights, diameters, age, etc., of a large number of specimens cut in the Adirondack forest, and excellent photographs, may be found in the Report of the New York State Forest Commission for 1894, where the monograph by Mr. W. F. Fox on the Black Spruce refers to the Red Spruce as now understood, and which is also locally known as Yellow Spruce. On high mountains, at the limit of tree growth, the Red Spruce may be reduced to a low plant scarcely rising above the shelter of the rocks. Growing in the woods the Red Spruce becomes a tall, straight tree without living branches, except on the upper part; in open places it may grow up symmetrical in form and covered with nearly horizontal branches to the ground. The general color of the foliage is dark yellowish green, varying to dark green, in this respect resembling the commonly planted Norway Spruce or the Oriental Spruce, *Picea orientalis*, more than any of our native species. The leaves are either straight, or nearly so, or more commonly decidedly curved or bent and appressed toward the tips of the twigs. The small twigs average stouter than those of the Black Spruce under similar conditions, and they are not so inclined to droop or be so pendulous. The bark of these young twigs is of a brighter reddish brown color and is more or less densely covered with minute brown hairs.

The ripe cones, before opening, are oblong or oblong-oval in form, the middle, or the upper half stoutest, and tapering to the apex from near the middle, instead of being slender and nearly cylindrical, as are the cones of the White Spruce, or plum-shaped or ovate like those of the Black Spruce, and they have very short curved stalks, shorter than those of the Black Spruce. They seem to be borne nearer the tips of the branches than the cones of the Black Spruce, and rarely persist on the trees longer than

the second summer. On different trees the cones may vary from an inch or an inch and a quarter, to two or occasionally nearly two and a half inches in length. They may be green or purplish in the growing condition, but as they become ripe and dry and the scales separate they lose their purplish aspect and change to a bright reddish brown color. The scales at the apex are broad, rounded or rarely obscurely pointed, and they are quite firm and rigid, and have edges entire or only minutely eroded or notched.

Lambert, in his monograph of the genus *Pinus*, published in 1803, appears to have given the first unmistakable figure of the Red Spruce, accompanied by a description which is relatively not so good as the figure. To this species, in accordance with the generic classification of the time, Lambert gave the name of *Pinus rubra*, which was afterward placed in the genus *Picea*. As Miller, in his *Gardeners' Dictionary* (eighth edition, 1768), previously used the name *Pinus rubra*, and seems to have applied it to *Pinus sylvestris*, the Scotch Pine, it is likely that our Red Spruce is to be burdened with another name to conform to rules adopted by some of our botanists. It may be that the name *Picea Canadensis*, applied to the next species by Dr. Britton, rightfully belongs to the Red Spruce. If the name *Picea rubra* must be done away with, and if the name *P. Canadensis* cannot be applied to this species, perhaps botanists may see the propriety of taking up Muenchhausen's name (*Pinus Abies acutissima*; *Der Hausvater*, vol. v., p. 225, 1770) if it is conceded that he was describing the Red Spruce. The species would then become *Picea acutissima*, a name much less appropriate than the one by which it is now known. Muenchhausen describes the tree as having reddish bark, but otherwise much like the Black Spruce, of which he also considered the Red and White Spruces as possible varieties. He gives as English names of the Red Spruce, "The Red Spruce Fir, or small-coned Virginia Fir, the new Scotia Fir with oblong cones."

The third Spruce of eastern America is the White Spruce, *Picea alba* of most botanies, and which may be changed to *P. laxa* if the name *P. Canadensis* does not surely belong to this species. It is locally known in New England as the Bog Spruce, Cat Spruce and Skunk Spruce. The last two names have been given on account of the strong peculiar odor of the foliage when rubbed or bruised, or which, in certain states of the atmosphere, may be detected at some distance from the trees. This species is native only in the northern United States and in Canada, extending from the Atlantic coast far westward.

Dr. Britton, in the *Catalogue of Plants growing within one hundred miles of New York City*, published in 1888, and in his new *Flora*, has fastened Miller's earlier specific name of *Canadensis* (*Abies Canadensis*, *Gardeners' Dictionary*, eighth edition, 1768) to this species; but, except for the fact that Miller calls it the "Newfoundland White Spruce Fir," there seems to be no more authority for applying Miller's name to the White Spruce than to the Red Spruce. Indeed, the brief description might apply to either species. Moreover, Miller, who did not recognize the Red Spruce as such, also says that his species is used indifferently with the Black Spruce in the manufacture of spruce beer. Now, it is well known that the White Spruce, on account of the strong disagreeable odor already mentioned and the equally unpalatable flavor, is never used in making spruce beer. As what is called White Spruce in many English collections to-day proves to be our Red Spruce, there is good reason to believe that Miller had the latter before him when he wrote his description. In addition to his description he gives a figure of the species in his *Figures of Plants*, published in 1771 (vol. i., plate 1), and, although very poor, this certainly bears more resemblance to the Black or Red than it does to the White Spruce. In this volume, page 1, he says, "the leaves of the Black sort are whiter on their underside than those of the White," and also that "the White is always found growing naturally on the mountains, and the Black upon the low grounds, generally in bogs or swamps. The first is by much the largest tree." These comparisons are

quite applicable to the Red and Black Spruces, and his further statement that "the cones of these trees were sent from Virginia by Mr. Banister toward the end of the last century," points to the Red Spruce, for he would hardly have obtained the White Spruce from the region indicated, even allowing for the very large and indefinite Virginia of those early days.

The evidence attainable certainly seems to show that the name *Picea Canadensis* should be transferred to the Red Spruce, and that the White Spruce should be called *P. laxa*, as proposed by Professor Sargent (*GARDEN AND FOREST*, ii., 496.).

Besides its peculiar odor and flavor, the White Spruce is distinguished from the Red by its distinctly glaucous or dusty-looking foliage and by having leaves longer and generally more pointed than either the Black or Red Spruces. The twigs are stout and rigid, pale greenish white, and are glabrous or without the hairs which are found on the other two species. The mature cones on different trees may vary from an inch and a quarter to two inches and a half or more in length. They are slender and more or less cylindrical or finger-shaped, green while growing and pale brown when ripe and dry. They appear sessile on the tips of short twigs and ripen early in the autumn, when the scales separate and allow the seeds to escape. The scales are quite broad, and are either rounded or truncate, or even slightly retuse at the apex. They are smooth, and the edges are entire and not notched or eroded, although some of the scales are occasionally split down the middle of the outer end. They are very thin and pliant, and the whole open cone is easily crushed in the hand, unlike the scales of the cone of either the Red or Black Spruce, which are firm and rigid and not easily crushed down after the cone is dry and open.

Growing in open places the White Spruce becomes a large tree of symmetrical conical form with horizontal branches from base to top. As in the case of the Colorado Blue Spruce, the glaucous or "blue" character of the foliage may vary considerably in different individuals, some trees showing it in much greater degree than others. Rarely, specimens of the Red Spruce may be found having a slight glaucous hue. The leaves of all the species vary greatly in length, thickness and sharpness of their points according to the part of the tree upon which they grow, to environment, to the age of the trees and to other conditions.

The winter buds of the White Spruce are usually of a lighter brown color than those of either the Black or Red Spruces, and are larger and composed of broader scales, which are generally loose or flaring at the tips, while those of the other two species are much darker-colored, are smaller, and have narrower, more closely appressed scales, so that their buds are more conical or pointed.

While the specific differences are so confusing in the early as well as some of the later literature on the Spruces, the three species are well figured in the first volume of Lambert's splendid monograph, which was published in 1803. Plate 28 shows the Red Spruce, which was figured from specimens grown in England at that time, but on the same plate are two "ripe cones imported from America by Mr. Loddige," which seem much like those of the White Spruce. The three species are also well represented in the *Pinetum Woburnense*, published by Forbes in 1839.

## New or Little-known Plants.

### *Aster junceus*, Ait.

THOUGH a rare plant in the United States, *Aster junceus* has been better understood than the related *A. longifolius*, which was discussed in a recent number of this journal (vol. ix., p. 507). In 1841 Torrey and Gray gave to a discussion of this species, then treated under *A. laxi-*

*folius*, Nees, a full page of their *Flora of North America*, and to-day, with additional material at hand, there is little to add to their characterization of the plant.

Like *Aster longifolius*, this species is of northern range, but it extends farther south, to central New York, Ohio, Michigan, Wisconsin and the Black Hills of South Dakota. It is generally found in sphagnum swamps or on gravelly shores, though it sometimes grows on drier soil. From a large number of herbarium labels it would seem that *A. junceus* has a remarkable period of bloom, from late June to early September, a habit which was long kept in mind by the name *æstivus*, applied to this plant.

*Aster junceus* is ordinarily a well-marked species. The smooth or slightly pubescent, or even roughish, stems are very slender, growing from one-half to three feet high. The thickest leaves are linear or elongate-lanceolate, attenuate to the tip, but hardly narrowed below to the sessile base; the cauline are from two to six inches long and from one and a half to four lines broad; the floral are much reduced. The leaves are, further, quite entire, or sometimes a little serrulate, the margins generally being recurved and strongly ciliate-scarious. As in *A. longifolius*, the branches of the inflorescence vary in length; the heads may be few or solitary on the short branches, or loosely paniculate at the ends of the slender, almost naked branches. The heads are about three-quarters of an inch across. The involucre is three or four lines high, of about three series of slightly imbricated, erect, linear or linear-lanceolate bracts with acute or attenuate herbaceous tips. The rays vary in color from white through pink and crimson to deep violet-blue, but commonly they are pink or crimson.

Though *Aster junceus* approaches *A. longifolius* in some of its forms, it can generally be recognized by its lower and more slender habit, narrower, thickish and scarious leaves, and by the shorter imbricated involucre with no enlarged outer foliaceous bracts.

Mr. Faxon's drawing (see fig. 9, p. 65) was made from a specimen collected at Fort Fairfield, Maine, where, in early September, with the dim purple spires of *Prenanthes racemosa*, the creamy white stars of *Parnassia* and the golden-yellow masses of the shrubby Cinquefoil, this *Aster* makes of the gravelly intervals of the Aroostook River a garden of delights for all botanists who have found their way to that favored region.

Gray Herbarium, Cambridge.

Merritt L. Fernald.

### *Ipomœa Briggsii*.

THIS plant, introduced a year or two ago, has proved a first-class winter-blooming climber, but so far, in this neighborhood at least, it has resisted all efforts to induce it to bloom out-of-doors during the summer. This failure to show summer flowers is not to be regretted very much since it does so much to brighten up the conservatory during the dull season. Last spring I planted several good-sized tubers out-of-doors in company with other tuberous sorts. *Ipomœa Briggsii* made splendid growth, but no appearance of bloom; about the beginning of October the tubers were carefully lifted and put in pots, some of the branches which had got mutilated in the operation were removed, or where these were too numerous for the roots to carry over after potting they were thinned out a little. A sunny position was given to the plants in the Begonia-house, where in a few days the shortened growths freshened up. A few new shoots started out, and then from the axils of the leaves the flower-buds began to show. It is now three months since the first flowers opened, and several flowers have expanded on each plant every day since. Unlike our summer-blooming *Ipomœas*, which close their flowers early in the day, those of *I. Briggsii* remain open all day long.

This species resembles *Ipomœa Horsfalliæ* to a certain extent. Its flowers, however, are smaller, and their color may be called a rich magenta crimson. Next season I intend

Fig. 9.—*Aster juncus*, Ait.—See page 64.

to grow it in large pots plunged out-of-doors, so that the plants can be removed to the greenhouse without having to cut any of the branches. Cuttings of the ripe wood root much more readily than those of *I. Horsfalliæ*.

#### Propagating Plants by Cuttings.

THE propagation of plants by means of cuttings or slips is the simplest and best known. Almost all plants can be multiplied in this way when properly treated at the right time.

In any special instance one ought to know the conditions under which the plants exist, especially as to temperature; and the season of active growth, for this is generally the best time to start the cuttings or slips, especially of the so-called soft-wooded plants. There are some exceptions among hard-wooded plants, which seem to need a longer period of preparation or callousing. We can strike cuttings almost any time from the growing shoots of Roses, but slips of ripened wood must be treated as we treat Grapevines and Currant prunings, by putting them in sand in cold frames or cellars to callous over winter. A large number of hardy shrubs can be propagated in this way, and we get larger plants in less time than when we use the soft growth. Whenever soft tips fail to root it will be well to try ripened wood in the way suggested.

Soft-wooded plants are propagated mostly during winter-time. In many large establishments only poor provision is made for propagating. It is not at all uncommon to see cuttings standing in pots on ordinary greenhouse benches, under adverse conditions, making a struggle to gain a root-hold. No greenhouse should be without a corner properly fitted for rooting plants. This can easily be done. In the majority of places, the benches are of wood or slate slabs, and if we would enclose a section of a bench by boarding up the under part we could get sufficient warmth even for tropical plants. Slides will be required to regulate the temperature. Our benches being of concrete we could not adopt this arrangement, and in such cases the best plan is to tap the heating system and carry a coil of three-quarter-inch pipes above, so that they rest on the table. These pipes must be boarded over so as to enclose an evenly heated air-space, which in turn evenly heats the bed of propagating sand above it. This is better, of course, than to run the pipes directly through the bed. Above this platform a part of the bench boxed in holds some four inches of sand. The box may be finished neatly or spanned by sheets of glass, movable as occasion requires. By a valve arrangement we are able to regulate the amount of bottom-heat to a nicety. In selecting a corner one should choose the shadiest and, if possible, the coolest place. Practical experience has shown that successful propagation requires that the temperature of the air should be about ten degrees lower than that of the soil or sand in which the roots form. A cool house enables us to make these conditions better than a warm one. A bottom-heat of sixty-five degrees, Fahrenheit, with an overhead temperature of fifty-five degrees, will suit all but a few tropical plants. The object should always be to develop as many roots as we can with as little excitement as possible of stem and leaf growth. A soft, spindling growth is least desired, but always results when we use a close, stuffy propagating bed.

Medium sand, neither coarse nor soft, is best. I avoid red sand. For winter and spring work we like our sand as free from clayey or loamy ingredients as possible, though for summer use a slight percentage is advantageous. It should be packed firmly.

In the preparation of cuttings the old practitioners used to hamper their work by much detail. It was not supposed that a cutting could root unless taken off at a joint, and even to-day some growers are possessed by the same delusion. Special care is needed with some kinds of plants. Cuttings must be selected and be at just the proper condition of ripeness, but with the majority of the plants propagated cuttings made of sturdy growing shoots are almost sure to root, no matter where we cut them. All that is necessary is to see that they are properly inserted, and with as little delay as possible. They should be cut clean, shorn of a few of the bottom leaves and made firm in the sand. Abundance of water must at once be given and the bed well shaded, for on no account must the cuttings be allowed to wilt.

Of soft-wooded plants it will suffice to mention a few which require special preparation or to be in a certain condition of ripeness. Growing side-shoots of *Ficus elastica*, taken with a heel, root more quickly than the tips. It is possible, also, to root separate eyes of these, but it takes a very strong bottom-heat of eighty degrees to start them into growth even when rooted. *Daphne Indica*, *Cytisus*, *Azaleas* and *Acacias* root best from half-ripened shoots taken with a heel. To propagate these in quantity it is a good plan to prune an old plant closely and take the fresh shoots as they come from the older wood. *Euphorbia* (*Poinsettia*) *pulcherrima* and *E. fulgens* root best from soft shoots, also taken with a heel. Old plants of these kept in a dormant condition until the opening of spring, and then planted out when settled weather comes, furnish abundance of cuttings all through the summer, and from these we get a lot of various sizes. *Dracenas* of the *Cordylina* section seldom fail to root when the tips are taken as well as by division of the stem and root.

Wellesley, Mass.

T. D. Hatfield.

### Greenhouses for Amateur Gardeners.

THIS is the season of the year when plants commence to grow more naturally and force more readily in the greenhouse. It seems to be also the time when one's less provident gardening friends drop in on their annual visit to take measurements and talk over building that long-delayed greenhouse, and it is a good time to talk over the matter from the amateur point of view. No two persons garden in the same way and with similar ideas, but no one can garden seriously for any considerable time in this climate without feeling the need of shelter of some kind for his plants, many of which are safe out-of-doors for only half the year. Even those of us who are specially devoted to the cultivation of hardy plants, find that as our collections grow we need shelter for plants whose hardiness is uncertain, or for those which are to be planted out, but have been received out of season. One can possibly garden successfully with cold frames in a hardy-plant garden, but they are anything but pleasant things to care for during the stormy days of winter. Besides, one's garden fever seldom reaches an ebb where flowers are not acceptable, and in the pursuit of these and of comfort we naturally gravitate toward a greenhouse or a desire for one. Unfortunately, it is too often a desire, for, curiously enough, there seems to be a general idea that a greenhouse is a luxury, expensive to build and expensive to maintain. This is one of those popular fallacies which keep afloat mostly because no one takes the trouble to deny them, and perhaps because the horticultural builders have not recognized the fact that there is a very large want of small greenhouses at a moderate price. Such greenhouses are offered abroad for much less than half the prices quoted here, and heaters in great variety at prices which evidently have some relation to the cost of production. It will be a great boon to horticulture when the builders wake up to modern business methods and offer out of stock a choice of a few styles of small greenhouses at a fair price, suitable for modest gardens. At present, however, one does not need to debar himself if he is willing to take some trouble. By visiting the owner of some small house one can get some measurements and sketch out his special requirements. The lumber for the double-board walls is of small expense at the nearest lumberyard. The sash-bars can be ordered of those dealers who make them a specialty, and the ventilating sash can be had of some dealers. Any carpenter can soon frame the structure ready for the glass, and, in fact, the whole thing is not beyond the skill of any one handy with tools. Seventy-five to a hundred dollars' worth of materials will suffice for a house large enough for most small gardens, and another fifty dollars should put in a water circulation, which is the best and most economical method of heating. It is difficult to advise on the form of the greenhouse most likely to prove satisfactory; it will depend very much on the species of plants grown. Of course, the cheapest form is a span-roof over wooden walls, as it is the easiest and quickest built. The modest structure which answers my requirements is an evolution from this form, and may be suggestive to any one who is likely to grow almost anything except strictly tropical plants, and who wishes also to store plants which must be kept cool and dormant. Originally I had a house about eight feet wide with side benches, with heater at one end and pipes under the benches. Outside of the house to the south was a row of cold frames. It was borne in on me after some experience that covering and uncovering cold frames was not a specially pleasing occupation, and I had rather too much heat in the house. I then raised the sash, sloping it from the ridge to the front of the cold frame, and by digging a walk just outside the former wall of the house, but now under glass, I have access to the beds of the former cold frame, and can work over them at any time in perfect comfort. This annex is ordinarily ten to fifteen degrees cooler than the main house. At the furthest end plants remain nearly dormant, and in other places there is warmth enough to bring plants and bulbs on gradually as may be desired. Later I took out the cube of earth under the south bench and removed the lower part of the former south wall, adapting it to a fernery. At present, with a house fifteen feet wide, I have now fifteen feet width of benches and solid beds and two paths. A further improvement would be to carry the north wall up three feet so as to make room for shelves which would hold more pots. But the most satisfactory addition ever made to the house was a coat of emerald-green, which painted it quite effectually out of the landscape. There does not seem to be any special reason why such a utilitarian structure as a greenhouse should be made specially prominent by the whitest of paint. Small greenhouses and commercial places cannot be made very effective show places, but it does seem

as if there might be a reform in private establishments conducted on a liberal scale, where usually the machinery of pipes, benches and pots is more prominent than the plants. It would seem that such places would vie with each other more in producing effective ensembles than in the production of crops.

Elizabeth, N. J.

J. N. Gerard.

### Notes from the Botanic Garden of Smith College.

THE vigor and luxuriance of the Palms and other tropical plants in the Palm-house here seem to prove that the planting-out system is the best for making fine specimens in a short time, and we agree with Mr. Watson who, in a recent letter to GARDEN AND FOREST, says "that he would rather enjoy a healthy specimen for two years than put up with a miserable, half-starved scrag of a plant for twenty." The bed in the Palm-house here is forty feet long by twenty wide and five feet in depth; three feet below the path and two above. Underneath the bed is one and a half feet of broken bricks for drainage, and draining pipes pass through these. The soil is a sandy loam, being the top soil from the site where the greenhouses now stand, with two cords of rotted stable-manure and five hundred pounds of ground bone incorporated. The bed is raised two feet above the path, so that it will be warmer than it would be if kept on a level. The sides of the bed are kept up by rock-work with a gentle slope in to the bed. The pockets in the rock-work are planted with some thirty-five species of Ferns and Selaginellas, several of a kind, a few varieties of Rex Begonias and Ficus repens. Considering the heavy spraying they have been subjected to while spraying the large plants in the bed, the following list of Ferns and Selaginellas have done exceptionally well: *Doodia aspera*, *Nephrodium hertipes*, *Asplenium biforme*, *A. bulbiferum*, *Nephrolepis exaltata*, *N. Phillipinense*, *N. cordifolia*, *Davallia Fijensis*, var. *plumosa*, *D. Fijensis*, var. *majus*, *Pteris palmata*, *P. serrulata*, *P. Sieboldi*, *Polypodium aureum*, *Aspidium falcatum*, *Lastrea opaca*, *Doryopteris nobilis*, *Gymnogramma sulphurea*, *Adiantum caudatum*, and in open places *Lomaria gibba* and *L. ciliata*, *Selaginellas Kraussiana* and *Martensi*, the latter being especially well suited for this purpose. Many of the other Ferns planted have done well, but are not as thoroughly suited for the purpose as those in the list given. In addition, many Ferns have sown themselves from spores probably blown in from the adjoining house, and some of the native *Selaginella Apus*, with Mosses and Liverworts, came up spontaneously. These, with the Rex Begonias and Ficus, have almost hidden the rocks from view, and make a beautiful and much admired edging for the bed.

We have in the house some twenty-eight species of Palms, representing, as far as we have been able to get them, types of the different sections of this family, though not more than eight are planted in the permanent bed. Besides these eight Palms the bed contains three Tree Ferns of different species, namely, *Alsophila australis*, *A. excelsa* and *Dicksonia antarctica*; one *Ficus religiosus* and *F. elastica*, a large specimen *Codiaeum*, var. *Queen Victoria*, *Coffea Arabica*, *Ravenala Madagascariensis* or Traveler's Tree, *Bambusa arundinacea*, *Dracaena fragrans*, *D. australis*, a fine specimen of *Cyanophyllum magnificum* with leaves thirty-two inches long and seventeen wide, a clump of *Hedyclium Gardnerianum*, and one *Monstera deliciosa*. For undergrowth we have planted, nearer the outer edge, clumps of *Calathea zebrina*, three species of *Philodendrons*, some of the large-leaved Begonias, such as *B. ricinifolia*, *B. Verschaffelti*, *Curculigo recurvata*, clumps of *Aspidistra lurida* and *Peperomia arifolia*, which make fine plants planted out, also several varieties of *Codiaeums*, while in the centre among the Palms are some of the commoner species of Ferns and plants of *Sanchezia nobilis*, which do remarkably well used in this way. Three species of *Musa* have been planted so as to give the house at once a tropical effect. These will be removed as soon as the Palms attain a large size. *Musa Chinensis* is just now in fruit, the cluster containing about one hundred well-developed bananas, not quite ripe. This bed was planted toward the end of April last year, and I feel perfectly safe in saying that almost every plant has more than doubled its size.

On the side-tables, in addition to the young Palms already mentioned, are a small collection of Bromeliads and collections of ornamental-leaved tropical plants, flowering tropical plants, economic plants and plants of purely scientific interest. In baskets suspended from the roof are several species of *Nepenthes*.

The modern iron-framed greenhouses are excellent, but they have some disadvantages. Since the space under the

side-tables is all taken up by the hot-water pipes we have no opportunity for planting climbers, which add so much to the beauty of a house. Every experienced gardener knows how much better his ornamental climbing plants will grow when they can be planted out under the side-tables than when confined in pots or tubs. To overcome this difficulty we have planted them in boxes six feet long by two wide and one foot deep. These are painted an inconspicuous color and stand on the side-tables. The vines were planted last July and all have made good growth and some have flowered profusely. We have *Allamanda grandiflora*, *Bougainvillea glabra*, *Clerodendron Thompsonæ*, *Aristolochia elegans*, *A. Duchardii*, *Bignonia speciosa*, *B. Chamberlaini*, *Thunbergia Harrisii* and *Passiflora Pfordtii*, with space left for rarer species when they can be secured. All the vines are trained on horizontal wires placed about sixteen inches from the glass, to avoid any possibility of freezing.

Botanic Garden, Northampton, Mass.

### Water-lilies.

**How to Winter Them.**—Keeping Water-lilies through the winter is considered by many more difficult than growing them and producing first-rate flowers, but, as with many other plants, the more experience one has with the different varieties and their peculiarities the more simple their cultivation becomes. Of tropical or tender *Nymphæas*, medium to small tubers are the best to carry over winter, but it sometimes happens that it is desirable to retain a certain plant or variety that has made extra-large growth during the summer. I had several such last season, and by way of experiment I tried a new method of wintering. After the frost had cut off the foliage I awaited a mild spell, and then with a spade dug around the plant; I gave it a root-pruning, taking care to keep outside of the tubers, so as not to cut them; then with a spade on either side lifted the stool intact. This was again planted in the soil, which is sandy, under the bench in the greenhouse, and thoroughly soaked to settle the soil. After a few days the roots were much decayed, and another soaking of water was given to settle the soil around the old crown and attached tubers. In this condition they were left, and on examination at this date, February 2d, the tubers were in excellent condition and will remain so for a long time. Even the hardy varieties treated in this way are keeping better than I had expected. This treatment is not so well adapted to large plants of the *Stellata* type, as they do not form side-shoots and tubers. The best method for carrying these over winter is to keep them growing. These, though very large, were severely root-pruned, the largest leaves taken off, and potted into as small a pot as would hold them, which was ten inches. The plants have kept growing slowly, and are now fine and healthy with flower-buds. The water has been at a temperature of from sixty to sixty-five degrees, which is the temperature of the house.

**Winter-flowering Aquatics.**—Such varieties as *Nymphæa stellata*, *N. Zanzibarensis* and *N. pulcherrima* have been in bloom all winter. The latter variety is the best of any of the blue forms. The flowers open quite early in the morning, and remain open until late in the afternoon, whereas those of *N. Zanzibarensis* seldom, if ever, open until noon or shortly before. Little can be expected in the line of Water-lily flowers during December and January, but *N. delicatissima* and a seedling much like *N. Smithiana* have not failed to produce flowers of good size and substance. *N. O'Marana* has proved a disappointment. It was hardly recognizable as the plant which I saw in such good form, condition and color out-of-doors last summer. *N. Devoniensis* and *N. rubra* are better.

*Aponogeton distachyon* proves a first-rate winter-flowering plant. It enjoys a temperature of fifty to sixty degrees, and blooms freely all through the dull, sunless days. The flowers are sweet-scented, resembling hawthorn, and are good for cutting.

**Seed Sowing.**—We have decided to raise some Water-lilies from seed, and as it takes between three and four months to grow a flowering plant from the seed, the sowing must be done at once, of both hardy and tender varieties. Four or five inch pots should be used for the purpose and sandy loam. If the latter has lain some time and had manure composted with it so much the better, and fresh manure should not be used. The seed should be covered lightly after it is sown and the pots stood in water until the seed is thoroughly soaked. The pots should be submerged so that the tops are two inches below the water. Attention to this particular is necessary, or the seed will not germinate. The temperature of the water should be from seventy-five to eighty degrees. *Victoria regia*

seed may be sown now, but the temperature of the water must be eighty-five to ninety degrees, and from twenty to thirty days is required for germination. The young seedlings should be transplanted at an early stage and kept steadily growing. They must be repotted singly before they are weakened by overcrowding and by starving conditions.

Riverton, N. J.

W. Tricker.

**Cypripedium Morrisianum.**—This is a distinct and pretty hybrid, the result of a cross between *Cypripedium Harrisianum* and *C. Leeatum giganteum*, one of the finest and largest flowered forms of *C. Leeatum* in cultivation. The bloom is brilliantly colored, of excellent shape and substance, the dorsal sepal measuring over two and a half inches across, quite flat, with a broad white margin, faintly suffused with rose, the base of which is deep bronzy purple, having numerous lines of a lighter shade emanating from the base, which are profusely marked with minute purple spots. The inferior sepal is a clear pea-green, with several lines of a deeper tone; the petals are broad, measuring three-quarters of an inch in width, the edges closely set with numerous hairs, becoming very dense at the base, the whole a rich sherry-brown. The pouch closely resembles that of *C. Harrisianum*, and is of a rich deep purplish brown. The plant partakes of the character of both parents, having charming tessellated foliage. It has been named in honor of Mr. J. Morris, who has charge of the valuable collection of *Cypripediums* owned by Hicks Arnold, Esq., of this city. It flowered for the first time in F. Sander & Co.'s nursery, St. Albans, England.

## Correspondence.

### Some Rare New Jersey Plants.

To the Editor of GARDEN AND FOREST :

Sir,—*Lygodium palmatum*, the lovely and somewhat rare climbing Fern, was known to grow in quite a number of localities in this state at one time. Many of these Ferns are now destroyed. In the fall of 1894 I rediscovered the plant near Haddonfield, Camden County. It was growing abundantly among the Alders and Cornels that fringe a small brook, climbing to a height of four feet. It is very graceful and delicate in appearance, but the abundant growth indicated that it was perfectly at home.

*Arenaria lateriflora* is found quite abundantly on the sand-hills below Atlantic City. Some of the dunes have a complete carpet of green formed of its trailing stems and foliage. The fact of its being evergreen was unknown to me until this winter, when, having occasion to use some of the plants, I visited the locality (about one mile below Chelsea). I was at once struck by its beauty and adaptability for planting under trees in exposed sandy seaside places. It blooms quite freely in spring, the small white flowers resembling some of the *Stelarias*.

A rare and very peculiar plant is *Clitoria Mariana*. It appears in isolated places many miles apart, sometimes diligent search failing to reveal more than a single plant. I have always found it on quite dry sandy land.

*Desmodium rotundifolium* is a very ornamental trailer as it grows here. The habit of the plant is entirely prostrate, the large, perfectly round green leaflets covering the ground completely. It seems to thrive under trees where the shade is very dense, and I have often found it in full exposure. A single plant often covers a space two feet across.

Hammonton, N. J.

F. L. Bassett.

### More About Choke Cherries.

To the Editor of GARDEN AND FOREST :

Sir,—I was very much interested in the letter of Professor Card which appeared in your issue of February 3d, on "The Choke Cherry in Cultivation." I send you this note to corroborate the statement of Professor Card, and to say that in the clay flats of the Province of Quebec, bordering the Richlieu and St. Lawrence rivers, the Choke Cherry is one of the principal fruits cultivated by the French habitant. This is owing largely to the character of the soil, which is of the pronounced blue-clay stamp and of the stickiest and most impervious type. In this region the Choke Cherry may be found in almost every French garden. It is cultivated mostly in tree form, and multiplied by means of the suckers which spring up about the roots. A great many variations occur. Fruit large and small, light and dark, astringent and non-astringent, may be found. Two years ago I found a tree bearing large clusters of yellow-

ish white cherries. I have sown the seed of these and am watching the young seedlings with interest, hoping that improved forms may appear. The French use this fruit in many ways, but it is most largely partaken of uncooked, next as preserves, while a smaller proportion is made into jelly. The tree is hardier than the Wild Black Cherry, *Prunus serotina*, and is found all through the north-west territories, even upon elevated portions of the foot-hills of the eastern Rockies.

Central Experimental Farm, Ottawa, Can.

John Craig.

## Meetings of Societies.

### Western New York Horticultural Society.—II.

WE conclude our report of this meeting of fruit farmers by giving the principal points in two other addresses :

#### THINNING APPLES.

This was the theme of Professor S. A. Beach, and a timely one, since the overwhelming crop of the past year has seemed to some growers as much of a calamity as the attacks of fungous diseases or the ravages of insects. Since prices for the crop did not cover the cost of packages and the labor of picking and handling the fruit, Professor Beach argued that it would have been good economy to have thinned the crop so vigorously as to reduce the total yield and increase the amount of fruit of the first quality. This is not merely a theoretical view, since some tests conducted by the Geneva Experiment Station, in Ontario County, indicate that, besides relieving the market of inferior fruit, thinning has a marked influence on the productiveness of the trees in succeeding years. In these tests trees of the same variety as nearly alike in all respects as possible were paired for comparison, the fruit on one being thinned and the other left untouched. The thinning was tried in three ways: (1) all wormy, knotty and inferior fruit was removed and all clusters reduced to one apple; (2) in addition to this fruit-culling the remaining fruit was once more picked over, so that the apples left were not less than four inches apart; (3) same as the first treatment, with the remaining fruit thinned to leave apples not less than six inches apart. Trees of Baldwin Apples treated by the first method gave sixteen per cent. less fruit of all grades, and ten per cent. more fruit of the first grade, than the corresponding trees not thinned. Under the third method Hubbardston trees gave twenty-five per cent. less fruit, but seventeen per cent. more first-grade fruit. Greenings, which were heavily loaded in 1895, bore a good crop in 1896, but were not overburdened, and needed comparatively little thinning. Under the second method they gave six per cent. more fruit and ten per cent. more first-class fruit than unthinned trees. In all these tests about one bushel of culls was found on the trees, which were thinned to three bushels where the fruit was not thinned; while in all grades the thinned fruit was clearly superior in size and color to fruit of the same grade not thinned. The first grade included no apple less than two and a half inches in diameter, and the proportion of the apples which measured above two and a half inches was much larger where the fruit was thinned than where it was not, so that No. 2 apples from trees that were thinned were superior to the same grade from the trees not thinned. It was estimated that the fruit from the trees picked over would bring from ten to fifteen per cent. more in market than the same grade from trees which had not been picked over. Taking these results, the second method of thinning was enough superior to the first to more than pay for the extra work involved. Accurate data for comparing the second and third methods are not at hand.

It is too early to report precisely the effect of this treatment on next season's crop, but the experiment shows a marked improvement in the size and color of the fruit where the overloaded trees were severely thinned. These results are not surprising, and the experiments were hardly necessary to demonstrate them. The questions which remain to be determined are (1) whether it is possible to so control the productive energies of Apple-trees that they will usually bear every year rather than every alternate year, or even less frequently; and (2) if so, whether the results will warrant the expense of the extra work involved. It is well known that the thinning of peaches and pears makes a marked difference in the size, color and quality of the remaining fruit, and there is no doubt that apples on an overloaded tree cannot mature so great an amount of large, well-colored fruit as one which bears a moderate crop under the same conditions. The production of a great proportion of very large fruit seems to depend on the ability of the tree to furnish nourishment to the individual branches or fruit spurs.

The tree may be looked upon as a machine for manufacturing plant substances out of crude materials obtained from the soil and air. The work is done in the green portions of the plant, almost wholly in the leaves. In the presence of warmth and sunlight the crude material enters with the sap through the root, rises to the leaves, and with other material taken from the air it is built up into starch, sugars and other compounds which go to sustain the life and the growth of the plant. The total amount of such product which a tree can manufacture in a season is largely determined (1) by the amount of available plant-food in the soil, (2) the amount of foliage which continues healthy and vigorous throughout the season, (3) the total amount of sunlight and temperature favorable for the growth experienced during the season, (4) by a certain factor which may be called individual capacity and vigor of the tree. The amount of food material which a tree can supply in a given season for growing a crop of fruit is therefore largely fixed by the conditions last named and the amount of reserve material which was stored up in the tree the previous season for future use. After an Apple-tree has reached maturity the forming of fruit-buds during the latter part of each season is a perfectly normal process which will take place whenever the tree has sufficient nourishing material to supply this demand in addition to sustaining its growth, ripening its wood and providing leaf-buds for the coming season. The fruit grower may provide to some extent for the formation of fruit-buds each season by directing to that end the favoring influences so far as they are under his control. The foliage may be protected from attacks of disease and insects by spraying, so that it can elaborate the food material essential to developing the various plant tissues. By tillage and fertilizers enough plant-food in readily available form can be provided in the soil. By judicious pruning the amount of bearing wood may be regulated so as to reduce the labor of thinning the fruit, and sufficient light may be admitted to the inner and lower branches to help the leaves in manufacturing substances essential to the growth of fruit. Finally, by thinning the fruit so as to prevent the prodigal waste of the resources of the tree in seasons naturally favorable to excessive yield, the trees may be brought into more regular bearing, and in the end a much larger amount of first-class fruit can be produced. It may be objected that it is impracticable to thin apples because the fruit does not ordinarily bring a sufficiently high price to cover the cost of extra labor, and this is perhaps the most serious objection to the practice which presents itself to practical growers. Questions as to the best way of doing the work must be settled by practice in accordance with local conditions. Mr. Charles A. Green has written to *The Rural New-Yorker* that he took off from one-third to one-half of the fruit on a tree in a short time with an ordinary steel garden rake. Mr. T. Greiner has suggested in the same paper the shaking off of fruit and whipping it off with long poles. Both men admit that these methods are crude, and, no doubt, they suggest them simply because they are inexpensive. They are objectionable because no discrimination can be used as to the kind of fruit which is removed. Besides this, they cannot be used in June when the largest apples are no more than an inch and a half in diameter and the trees must, therefore, carry their full burden till later in the season before the fruit is large enough to be raked, clubbed or shaken off. The energies of the tree are thus wasted, and the fruit which is left cannot be expected to show as great an improvement as when thinning is done earlier in the season. More careful methods must eventually be adopted before thinning becomes an established practice.

It is well known that the lower branches and shaded parts of the tree bear a larger proportion of fruit inferior in color, size and quality than the branches which have more light. Most of these lower branches may usually be reached from step-ladders or racks fastened on wagons so that the parts of the tree which most need to be thinned can be reached with comparative ease. It would seem that by some such method a large part of the thinning could be satisfactorily done with cheap labor under experienced supervision. It should be remembered that the increased value of a crop is not the only item to be credited to the practice of thinning. It costs considerable labor to prop the branches of trees and save them from breaking under excessive burdens, and this goes to counterbalance the expense of thinning. Besides this, in an unthinned crop a large amount of inferior apples must be handled at little or no profit, or possibly at a loss. The ripening of this inferior fruit practically shuts out the possibility of a crop the next year. Looking over the season of 1896 we see broken trees and broken prices. Looking forward to the season of 1897 we see barren trees, with prospects of good prices. And after all the labor the late great crop has imposed, and

the loss it has brought to many fruit growers, is it not worth inquiring whether the thinning of the fruit in 1896 would not have paid? Would it not have been better if half the second-class apples grown in New York had never been marketed? If throughout the apple-growing sections half the seconds and all the culls had been thinned out early in the season, the remaining crop would have been exceptionally fine, and New York would have sustained the reputation for fine apples, which would be a material help in marketing succeeding crops. Besides this, having exceptionally healthy foliage and a favorable growing season, it is reasonable to expect that the partially unburdened trees would have provided fruit-buds for at least a fair crop next year.

#### PLANT-FOOD IN SOIL.

Professor Roberts read a paper entitled "An Inventory of the Land," which was a study of the productive power of soil. From a number of analyses he found that, on an average, eight inches of surface soil contained of potential plant-food to the acre 3,053 pounds of nitrogen, 4,219 pounds of phosphoric acid, 16,317 pounds of potash. This means so large an amount of the necessary elements of plant-food that one wonders why we do not secure larger crops and why we need to manure the land. Of course, with our present methods of tillage a very large percentage of this plant-food is not available, and the problem is how to treat this dormant food so that it can be used by the growing plants. The first consideration which impresses Professor Roberts is that it is not lack of food in the soil so much as lack of moisture which causes plants to languish. The prime object of successful tillage then ought to be to make the land a reservoir for the storage of moisture and to so treat it by stirring the surface as to prevent its evaporation, or, in other words, to compel it to pass off through the plants and do its work in supplying them with food. A number of experiments made during 1895 and 1896 on land of light and gravelly texture in cultivation without the use of any fertilizers seem to prove that large crops of potatoes, say 350 bushels to the acre, could be grown by cultivating between the rows so frequently as to pulverize the soil and liberate the plant-food. Of course, if there had been more rain there would have been better crops, but the tests seem to show that the soil could be so worked as to release as much plant-food as the crop could digest. At all events, it is Professor Roberts' belief that there is enough inert plant-food in the soil which can be made available by a little extra expense in tillage and cultivation, and that by the same method in ordinary seasons enough water can be preserved in the soil to develop a paying crop.

#### Notes.

During the first week of this month 47,000 bunches of bananas were received at this port.

During the fiscal year ending June 30th, 1896, 376 publications were issued by the United States Department of Agriculture. Exclusive of reprints these publications comprise 10,170 pages, and the total number of copies of all of them was 6,561,700.

At the more elaborate dinners and balls given by wealthy society people this winter the chief decorations have been of costly Orchids interspersed among the fronds of *Adiantum Farleyense*. *The Florists' Exchange* tells of one dinner table laid for thirty-two covers which was decorated with five hundred flowers of *Cattleya*, 2,200 of *Dendrobium* and 200 spikes of *Lælia anceps*, laid in a foundation of *Adiantum Farleyense*.

The new white Rose, Lillian Nordica, for which Mr. M. H. Walsh, of Woods Holl, Massachusetts, received a certificate of merit from the Massachusetts Horticultural Society last year, was exhibited at a recent Saturday meeting of the same society in Boston and attracted great attention. The flowers have long, straight stems, rich dark green foliage and exquisite fragrance. The seedling blooms freely and is from Margaret Dickson crossed by Madame Hoste.

As we stated last December, Albemarle Pippins have been uncommonly scarce this season, the entire crop in Virginia amounting to but 1,000 barrels. Most of the single car-load of this fruit which came to this city was exported, but the English supplies of this favorite apple have been mainly of the similar Newtown Pippins, from the Hudson River district in New York state. Five car-loads of Newtown Pippins recently reached this city from Oregon and California, and these, carefully repacked in boxes holding a bushel, have been shipped to London, where they have been pronounced the best apples of the kind seen there this season. They have realized as much as \$5.50

a bushel, a remarkable price in any season, and especially so when nearly two and a half million barrels of apples have been exported to Great Britain from the United States and Canada since last August, and with the best Baldwin and other standard varieties selling in England now for \$2.50 to \$4.62 a barrel.

At the recent conference on the occasion of the tercentenary of the introduction of the potato Professor Johnson spoke of the value as a substitute for the potato of *Stachys tuberosa*, a vegetable which is growing in favor in England, France and Switzerland. Somehow American gardeners do not seem to take much interest in its cultivation, although it contains eight times as much nitrogen as a potato of the same weight and a large quantity of a carbo-hydrate called galactan, which is more digestible than starch, being allied to dextrin, and therefore more easily converted by the digestive juices into sugar. For this reason the tubers of this plant would be especially useful for invalids and persons of delicate digestion, since they bear the same relation to the substance of the potato that peptonized foods do to ordinary meats.

Tests made in California as to the shrinkage of different varieties of prunes show that the small French prunes, thirty of which weigh a pound when fresh require seventy-five to the pound when cured, in round numbers, or, more accurately, the weight of the fresh prunes is to the weight of the prunes when cured as 253 to 100. In the large French prunes the ratio between the fresh fruit and cured fruit is as 291 to 100. Of the Robe de Sargeant variety the ratio was 278 to 100, while the ratio of the so-called Imperial prune of France was practically the same as that of the small-sized French prune, namely, 253 to 100. This Imperial prune is a trade name of a very fine French product, and the only variety which comes up to the standard is Imperiale Epineuse. This variety has but recently been introduced into California orchards, where it has proved of the very first quality. The leaves of the tree endure dry weather well, but it has not been planted long enough to demonstrate that it will be productive.

Some experiments recently made at the Massachusetts Agricultural College by Mr. Asa S. Kinney seem to show that a current of electricity will accelerate the germination of seeds. In a collection of seeds treated for twenty-four hours, thirty per cent. more germinated under the current than in lots untreated, and the seeds which received the electrical stimulus gave a higher percentage of germination than others. In many cases electricity seems to act a good deal like light does in its stimulating effect. It must be understood, however, that even if we admit this we do not know the best methods of using electricity upon plants in the soil, nor what strength of the current will probably secure the greatest growth. The range and the strength of the current which accelerates germination is found to be exceedingly limited. So far as these experiments go to form a basis of judgment, it would appear that the strength of the current which shows the greatest growth of radicles is equal to about three volts, where an interrupted induced current is used.

In the past two or three years not a few figs carried over by wholesale dealers until August, when they have become dry and unsalable, are then dipped into a thin syrup to freshen them. They are packed in fancy splint baskets holding a pound or more, enclosed with a muslin cover sewed on the edges, and alluringly stamped "Turkey." If sold at once before the arrival of the new crop and while yet in good condition, they are satisfactory to the uninitiated housekeeper, and are really rather improved by the harmless process. They are mostly sold by grocers and at second-class fruit-stands, and cost twenty-five cents a package. Kept too long they become moldy and musty. Recently a similar process seems to have been applied to a limited quantity of presumably new-crop figs, the fruit being then readily drawn out into its natural form, and labeled "pulled figs." These have been sold at the exorbitant price of fifty cents for a neatly packed box holding less than a dozen and a half of the fruits. In this case there is no good reason for the freshening, since the new-crop fruit still retains its own juices, and the effect is to make it bitter and not at all the delicacy it affects to be.

A Chicago florist has been selling fine Freesias with straight, stiff stems from eighteen to twenty inches long, and large, erect flowers, at \$3.00 a dozen, while the common run in the market are hard to dispose of at \$2.00, and sometimes at \$1.00. These Freesias come from the stock of ten years ago, when the flowers first began to attract attention, and the

bulbs are better than when they were first obtained. Ten or twelve are planted in a seven-inch pot, and after the flowering period is over the foliage is allowed to die off naturally, and then the plants are treated like Callas, being allowed to die down every year. When there is no longer any growth the pots are set under greenhouse stages and kept perfectly dry. About the first of August the bulbs are sifted from the earth and selected into sizes, and those of the same size only are placed in the same pot. For years they have come into flower about Christmas or New Year's, and by being placed in heat in succession they bloom until the end of February or the middle of March. Certainly this care is well repaid, and, cheap as Freesia-bulbs are, the purchase price is saved, and the bulbs are always on hand for early planting, which, after all, appears to be important for their successful growth.

Oranges from Cuba now sell at \$6.00 a barrel, wholesale, repacked. While very sweet, this fruit is not at all showy or attractive, the skin being coarse and dull-looking. The Havana fruit also has poor keeping qualities and must be sold soon after landing and used within a fortnight. The season for Jamaica oranges is almost ended, but 250 barrels having been received here during last week. Altogether, 254,080 barrels and 23,340 boxes of this fruit have come here since the first importations last September. But these heavy shipments have been carried on with very little profit to steamship lines and importers, and in some instances at considerable loss. Of 35,000 barrels of oranges which came from Jamaica in one week early in the season, all of the fruit was unripe and half of it spoiled from being gathered during rains and from careless packing. This want of care and judgment in picking, packing and shipping is said to be the cause of an unprofitable season when the outlook was highly favorable, owing to the scarcity of Florida oranges. The season for the latter is also closing; the best now sell for \$5.00 a box, at wholesale. Washington Navel oranges, from California, are the showiest of all citrus fruits now seen here, and are especially bright and clean; \$3.50 a box, at wholesale, is a fair price for this choice fruit, which is juicy and sweet. Of Mediterranean oranges, good Valencias sell for \$2.65 and Sorrentos for \$2.15, prices on Mediterranean oranges and lemons having advanced fifteen to twenty-five cents a box during last week. There are now 20,050 boxes of these oranges and 147,000 boxes of lemons on the way to this port. Grape fruit from Jamaica costs \$6.00 to \$10.00, and from Florida \$12.00 a box, at wholesale.

Dandelion is now coming from the meadows of New Jersey and from under glass, the forced plants being more luxuriant in growth, though not more tender. Both sell for fifteen cents a quart. Other offerings in collections of fresh vegetables are spring onions and leeks, chives in little clumps of soil, endive, chervil, fennel, watercress, mint, escarole, tarragon, parsley and sorrel. Well-grown shoots of rhubarb cost ten cents for a bunch of seven; Boston cucumbers, twenty-five cents each. Okra, from Cuba, costs ten cents a dozen, and peppers five cents apiece. Short plants of celery, from Rochester, New York, sell for seventy-five cents a dozen, and the longer ones, from California, beautifully blanched, for \$1.00, while the new crop from Florida commands \$1.50. The best cauliflower now comes from Florida, large perfectly white heads costing thirty-five cents each; those from California are yellowish after the long journey, and find slight demand. Large quantities of spinach and kale have been coming from Norfolk, Virginia, one steamer last Saturday bringing 1,400 barrels of spinach and 600 of kale, and the receipts of these two vegetables for the week amounted to 11,050 barrels. These sell at twenty cents a half-peck. Florida tomatoes cost twenty cents a pound, and those from northern hot-houses forty cents. String-beans are quite plentiful at twenty cents a quart, while southern peas are scarce, and some from California have sold at \$1.50 a half-peck. Bright, fresh eggplants cost twenty cents each, and new beets and kohlrabi, four in a bunch, ten cents, and among winter roots oyster plant and knob-celery may be had for the same price. Winter beets, carrots, turnips and parsnips are in regular supply. Cabbage, from Long Island, costs ten cents a head, and the red sort brings fifteen cents. There is also Danish cabbage in market, and new cabbage from Florida. Lettuce is coming from Boston hot-houses and from Florida and Cuba, and Romaine lettuce from Bermuda. Onions, from Bermuda and Havana, bring thirteen cents a quart. Bermuda potatoes sell for fifty cents, and sweet potatoes, from southern New Jersey, for twenty-five cents a half-peck. Mushrooms continue abundant, the best costing but fifty cents a pound. Hot-house asparagus is still a luxury, and commands ninety cents for a small bunch.

Tree Pruning.

TREES can still be pruned to advantage up to the time, now rapidly approaching, when the limbs are gorged with sap, so that they will bleed more plentifully than at other seasons. This loss of fluids does not operate to weaken the vitality of a tree to any serious extent, but as the sap runs down the bark and keeps it wet for a long time, besides preventing the adhesion of any coating over the raw surface, the spores of various rot fungi are apt to find a lodgment in the wound so that decay will set in. This loss of sap will make comparatively little difference in the case of small limbs, and it should not prevent the prompt removal of stem and root sprouts, for example, so that these will not continue to exhaust the energies of the tree another season. As a rule, late autumn is the best season for the general pruning of ornamental trees, because the leaves are then out of the way and the branches which cross and rub against each other can be detected. When the whole skeleton is made bare it is more easy to see which branch it is that projects in such a way as to make an unsymmetrical head and where the limbs are growing too thickly.

Of course, no one should be allowed to use a knife or a saw on a tree unless he knows exactly what he wants to accomplish by pruning and can tell why the operation will bring about the desired end. Some tree lovers are so sentimental that they look upon any pruning whatever as a species of cruelty. Others believe that every effort to make a tree shapely is unnatural, and therefore inartistic. But it can be easily demonstrated to the first class that, instead of inflicting an injury, the good pruner can add to the vigor and longevity of a tree, especially of one which for any reason has begun to show signs of feebleness. To the other class it may be said that the effort to keep the tree shapely and in its proper natural balance by pruning is quite a different operation from clipping it into a form unlike what it ever would assume if naturally grown. It is small wonder that persons who watch a gang of professional tree-trimmers moving their equipment of ladders and axes from one tree to another along a city street

shudder at the butchery they witness. These impostors often saw off every large limb a few feet from the trunk and leave only an occasional stub projecting from the remnants of these limbs, so that what was once a tree becomes a mutilated stump, and the very process which was intended to make it healthy and beautiful ruins it beyond any hope of recovery. Of course, street trees need pruning, but if they have been well selected at the outset a small knife will suffice to remove while they are young an occasional branch which starts from the wrong place, and if they are carefully attended to for some years rarely will any large branches need to be removed. While on the subject of shaping trees it may be remarked that on a broad lawn single trees never look as well as when their branches sweep the turf, and in most instances it is a barbarity to cut these away. Coniferous trees which grow in a pyramidal form, unless they are closely crowded in a wood, always branch close to the ground, and the removal of these lower limbs not only converts a beautiful tree into an unsightly object, but it almost certainly injures the health of such species as naturally grow in moist climates, for these low branches not only check evaporation from the soil and retain moisture about the roots of the tree, but they help to bring the centre of gravity of the mass nearer the base, and in this way enable the tree to better withstand the force of the wind.

We began this article, however, for the special purpose of calling attention to the fact that pruning can be used as a remedial or restoring process upon deciduous trees which have become decrepit. There is nothing new in this, and in the very first volume of this journal, and often since then, we have explained how trees which have begun to show signs of enfeebling age can have their youthful vigor renewed. When the upper branches of a tree begin to die, this means that for some cause the tree is receiving insufficient nourishment. When the ground has been pastured over and trampled upon, the food taken away by grass or crops and the tree neglected in every way, there is nothing that will so stimulate new life as vigorous surgery. More is needed than the cutting away of branches already dead. A tree on the decline should have its main branches all shortened in from one-third to one-half their length. What is needed is more leaf-surface, because the vital work of the tree is carried on in the leaves, where the plant food taken up by the roots and from the air is elaborated and transformed into growing tissue. These feeble branches carry nothing but small and scattered leaves which do not suffice to carry on the life-work of the tree with energy. But when a branch is cut away the tree at once exerts itself to throw out new shoots, and these shoots will bear much larger leaves, so that the leaf-surface of the tree will be greatly enlarged, while the amount of wood to be vitalized is decreased. Of course, such trees can be helped in other ways—that is, by covering the ground with ashes or well-rotted manure, or by giving in any other way a supply of food that is easily assimilated, but the pruning is the energizing factor in the process. Every one has noticed how vigorously a shoot will start from the root of a young Oak which is cut to the ground, and how the leaves will expand to accommodate themselves to the greater work imposed upon them, and prepare to utilize all the sap the roots will furnish. It is this same principle which will stimulate an old tree when its branches are pruned hard back to throw out new shoots and clothe them with abundant foliage.

We almost hesitate about repeating such an elementary injunction as that a branch should be cut off close beyond a healthy lateral, and yet it is a rule that we see violated every day, not only in ornamental plantations, but even in orchards. This lateral branch in spring will throw out a great number of leaves which supply themselves with sap which they can digest and send back to the very extremity of the amputated limb. If this extremity is painted over with coal-tar, or any other thick paint laid on with a brush, the wound will begin to heal over at once. On the con-

trary, if the amputated stump is left, so that the sap does not circulate to its extremity, it will necessarily die back to the point where the sap ceases to flow. This simple fact was illustrated in the first volume of this journal on page 349, with cuts taken from "A Treatise on Pruning Forest and Ornamental Trees," translated from the French of Monsieur A. des Car, and published in 1881 by the Massachusetts Society for Promoting Agriculture. A little reflection will show any one that as the living trunk or branch grows and envelops what is merely a dead plug, the tree will inevitably decay to the centre, for, as the rot fungus destroys the lifeless wood, water will soak in and carry these elements of decay deeper and deeper until the tree is hollowed out and finally made worthless.

All our native forest-trees take kindly to this treatment, and it was nine years ago when we wrote that most of them could be rejuvenated in this way. We then explained that decrepit Red, Black, White and Swamp Oaks, Black Birches, Beeches, Hickories and Elms had been thus pruned in the Arnold Arboretum where the trees in the natural woods were perishing from pasturage and from neglect. They were covered with dead branches, the foliage upon them was thin and poor, their dying tops showed that they had but a short space to live. It seemed important to save many of these old trees until a growth of self-sown seedlings could be brought on to replace them and a covering grown for the forest floor, and as some of these old trees were pruned each year those which had been operated upon first, or some six or seven years earlier, already showed in their dense dark-colored leaves and compact growth that pruning alone without any fresh soil or fertilizing material could put new life into a tree that was feeble and dying. Subsequent experience has confirmed the usefulness of this practice, and we can repeat our counsel with confidence, and advise all persons who have deciduous trees which have begun to fail to undertake the renewal of their vigor by intelligent surgery.

### The Chemise World.

OF all Californian shrubs or trees, the Chemise brush or Chemisal, *Adenostoma fascicularis*, gives most character to the landscapes of the Coast Ranges. What the Heaths are to western Europe, Chemisal is to California, and vast tracts of poor mountain lands are covered with thickets composed almost entirely of this one shrub.

Outside of the timber belt, which begins at Monterey and extends at intervals to Oregon, there is scarcely a mountain on the Coast Range of California, from San Diego on the south to Trinity, almost at the Oregon line, which is not in part covered by it. The greater the distance from the ocean the larger the percentage of mountain lands which this hardy shrub has taken possession of, until many sections of the eastern part of the Coast Ranges are almost entirely given up to it, and from the valleys to the mountain tops it holds a sway only shared by a few of the hardiest shrubs, Oaks and conifers. Many millions of acres of Government lands, which look so inviting on the maps, are but Chemise patches, and, as now, will always be a nomad's land, harboring only the deer and the coyote. Hardly a spot is too steep to allow it a foothold, hardly a soil too meager to afford it sustenance. Fires sweep over and leave blackened stubs, but with its unusual vitality it soon starts a new growth. In a few years rocks, hills and slopes are again masked by a close cover of blue-green which gives to the mountains a softness of outline peculiar to the Coast Ranges, and very beautiful, too, although the monotony of flowing lines often becomes tiresome.

Ukiah Valley is hemmed on the eastern side by a long, even-topped range of mountains. On the map they bear the Indian name of Mayacamas, being one of the numberless short ranges which form the jumble known as the Coast Range. The Mayacamas divide the chain of valleys, once lakes, of which Ukiah valley is one, from another

chain of lakes which are now slowly undergoing the same process of extinction. The largest of these is Clear Lake, a beautiful body of water, mountain-hemmed, thirty-five miles long, with a maximum width of eight miles. Next to Ukiah valley the range rises first in rolling foothills, which give way to steep grassy slopes interspersed with Oak woods, or occasional Chemise-covered barren mounds. Above the Oaks the upper range is to be seen as an endless succession of round-topped knolls or smooth slopes, all Chemise-covered, with the sky-line seldom broken by fringe of distant rock or tree mass.

If a more intimate knowledge of the high Chemise world is desired, access is not difficult. Many trails or wood roads lead through the Oak woods and the open ranges, and traveling is not difficult on foot or on horseback. Half-way up the mountains the Chemise is entered, and the hills which from the valley seemed covered with a smooth low coat are found to be tangles of dense brush from four to eight feet high, except where a fire has recently burned. Travel in the Chemise is of necessity pretty closely confined to the trails which have been made along the ridges by deer, Indians or hunters, and even on these trails it is not always easy. But let the hunter stray from the trail and he is apt soon to find himself in a thicket so impenetrable that he can neither force his way through nor crawl under, and it does not take a long experience in attempting to pull himself over the tops to convince him that the trail is the only satisfactory place for travel.

So year after year the Chemise grows, and by the not infrequent winter snows is pressed down more compactly, until some day a hunter, wishing to drive out the game or make for himself an easier passage, drops a match in the tinder underneath, and a fire is started which rolls over the hills in sheets of flames, making the grandest of pyrotechnical displays for the valley dwellers. Creeping among the dead leaves in thinner brush, it burns swathes for miles and finally dies out only when fuel is exhausted, it may be in days or weeks. Where the brush has been thick and the wind favorable only short stubs are left, but as often as not the leaves and twigs are burned and the stout stems remain a *chevaux-de-frise* almost as hard to penetrate as the original thicket, and even more destructive of good temper and clothes.

A favorite trail into the great expanse of Chemise between here and Clear Lake leads along the main ridge which divides the waters flowing into Russian River from those which, flowing at first into Clear Lake, finally find their way into the Sacramento River. This route, closely hemmed for miles by brush, gives constantly changing views of the beautiful Ukiah valley to the west, and of other valleys connecting with it on the north and the south. All about and to the east is a far wilder scene. For mile after mile, slope after slope, hill after hill, far-stretching ranges bear the same covering of Chemisal, and in the general view scarcely a shrub, tree or mass of rock rises above the lonesomely monotonous mass, except for infrequent groves of the straight and symmetrical west coast Scrub Pine, *Pinus attenuata*, on prominent points. Near at hand encircling ranges form a large basin which in turn is filled with a confused medley of lower ridges and hills. Rising head and shoulders above the wild Chemise region to the north and west, high snow-covered mountains can be seen, Pine forests ascending far up their slopes. The great dome to the north-east is Snow Mountain. In the middle rises Pine Mountain, a mass of conifers to its summit, while to the north the long ridge of San Hedrin can be seen. The long expanse of wild country is only broken by a tiny vale in the basin below. Among these thousands of acres of wilderness, perhaps forty acres form a rich little valley, watered by mountain springs and giving a good home-stead to a mountaineer. Like an oasis in a desert, it intensifies by contrast the loneliness of the surroundings. Desolate and barren it may seem, but I have found this wild region peculiarly rich in beautiful spots, and its inaccessibility shelters many a beautiful flower. Pretty little

valleys are hidden in the most unsuspected places, and the freshly burned-over Chemise is a rich field for the plant hunter.

A typical Chemise valley lies just north of Red Mountain, on which is the curious grove of *Cupressus Macnabiana* described in a previous number of GARDEN AND FOREST (see vol. ix., p. 233). Lost Valley is well named, for come upon it from which direction you may, it is a surprise. Two vales wind in sinuous curves through dense brush, and coming together form a broader vale containing a swamp of four or five acres. The little valley is closely hemmed by a dense growth of Chemise and Scrub Oaks, but not one intrudes into its grassy limits. Situated at about two thousand feet altitude, its climate is cool, and its growing season is at its height when in the valley below the dry summer has begun. Frosts come frequently and at all seasons, but the vegetation seems to have peculiar powers of withstanding them. Short Bunch Grass grows over the drier portions, and the swamp is a tangle of immense Thistles and Water Grasses, mingled in the fall with Golden-rod. Swamp plants follow the little watercourses. In July, *Lilium pardalinum* may be seen lifting its scarlet and yellow flowers above the weeds, and in late June handsome pale blue *Camassia* flowers in abundance throughout the wetter part of the place. Indeed, bulbous plants would quite possess the valley were they not kept in check by the gophers, whose underground passages are everywhere that the water permits. In June a blue *Brodiaea* grows in great abundance, and a little later *Calochortus lilacinus*, dwarfed as befits its high home, lifts its pretty lilac cups among the grass-blades. The tiny dwarfed plants and little cups of *C. venustus*, var. *oculatus*, which as the valley dries up are to be seen in the high portions, are little like the grand blossoms of the same plant in the valley below, and the rich purple tints seem unnatural. As little to be recognized are the small flowers and short leaves of the high mountain form of *Iris macrosiphon*, which is quite plentiful in the gritty soil next the side of the vale.

Nature is rich in oddities here. Down in the swamp a great Thistle grows; its woolly stems rise five or six feet high. The same plant grows in the higher parts of Lost Valley in a dwarfed form, the white leaves scarcely rising above the ground and the thick head set close down in them. The whole plant is more like a Cactus than the lofty plant of the swamp. Two *Godetias* abound in the late spring. *G. viminea* also grows below in the valley. It is one of our showiest plants, a lovely slender-stemmed annual, the flower having a red centre. The other *Godetia* has a pale, rather inconspicuous flower; it has a tendency to form round mats with many stems. All about the edge of the valley the soil is dry and gritty, and there can be seen large beds of our common St. John's-wort, a species with short stems six inches high and a very pretty yellow flower. It is one of the hardiest of flowers and thrives in the little dry openings throughout the Chemise country. We have few more delicately beautiful flowers. *Sisyrinchium bellum* is not uncommon.

I well remember a lovely lateral vale which I happened upon a few years ago. A fire had deadened the brush and invigorated the Columbines of the *Aquilegia truncata* type. There were hundreds of plants in full blossom, and so thick as to exclude all other species. This five-spurred flower is always beautiful, but I have never seen it to such advantage since nor before. In May the common Buttercup, *Ranunculus macranthus*, tinged the vale with yellow. Later there are many composites, and even in the fall the succession of bloom is kept up in the swamp and about the spring.

Four years ago the finest wood of *Pinus attenuata* I have ever seen stood on the slopes of the hill at the head of the valley, clean, symmetrical and straight-limbed, and as thick as the trees could well grow. A fire swept through, and now only bare trunks are left. With them, however, death is the beginning of a new and more abundant life. The fire that destroys the parents releases from their long

imprisonment in the cones the abundant seeds, which, falling in the still warm ashes, soon produce a more abundant growth. Now there are thousands of handsome young trees coming on. I have observed that this Pine is on the increase under prevailing conditions. It fruits at an early age, and fires seldom find it unprepared to perpetuate itself. It is of the hardiest constitution, and the seeds grow vigorously in the most barren of soils. Old trees of *P. attenuata*, gnarled, encircled by the persistent cones of many years and with dead limbs, can only be said to be picturesque, but many of the younger specimens are truly beautiful.

I suppose that of all of the shrubs of Chemise land, the Chemise itself, *Adenostoma fascicularis*, comprises fully ninety per cent. of the specimens. On the southern slopes, and on the less precipitous slopes to the west and north-west, it rules almost to the exclusion of all other shrubs. It belongs to the Rose family and is an evergreen with linear Heath-like leaves, a light-colored stringy bark and brittle wood. In late spring it produces an abundance of whitish flowers with green centres, and they are followed by seed-pods concealed by the tawny remains of the flowers which persist till fall. While it is overwhelmingly predominant in its realm, it lives on familiar terms with a great variety of shrubs or dwarfed trees as well fitted as itself to endure the hard conditions. On the driest ridges can be seen a stiff, spiny-looking shrub with small elliptic leaves, thinly distributed and grayish bark. In its season it has short racemes of very fragrant white flowers, which perfume the mountain wastes. This is *Ceanothus soledarius* in its high mountain form.

Here and there throughout the Chemise, in single tufts or in copses, the California Holly grows, or, as the Mexicans called it, "Toyon." It is an evergreen with large, glossy, serrated leaves. In midsummer it produces its white flowers and forms its paniced clusters of berries. These gain color as the season advances, and by the mid-winter holidays are a glowing wealth of crimson. For a long time the bright masses show against the dark foliage and lighten up the brushy expanse. On the highest ridges, where the summer heat is greatest and the soil the driest, and even the hardy Chemise takes on a stunted form, can be seen another extremely interesting shrub, *Pickeringia montana*, which is excelled by none of its Leguminous relatives when in full flower. At other times one sees a thin-leaved, stiff and spine-tipped shrub, often but four or five feet high, but sometimes twelve or fifteen. The bark is light green, the leaves ovate-lanceolate. It is very beautiful when the bush is a solid mass of pea-shaped flowers of a soft flesh-pink. Its season is quite long.

Ukiah, Calif.

Carl Purdy.

#### Leaf-spot of Pear.

FROM observations made during the past two or three years it has become apparent that what is called "leaf-spot" of the Pear in this country, and generally attributed to the fungus known as *Entomosporium maculatum*, is not wholly due to this fungus, but in many cases, perhaps the majority, is caused by an entirely different parasite. This emphasizes the need of expert examination of plant diseases when an occasion arises for writing upon these subjects, if one wishes to speak with as much accuracy concerning the name of the plant as would be desired when writing of potatoes. For some time I had been desirous of obtaining this fungus, *E. maculatum*, on the Pear in the vicinity of Ithaca, for a study of its life-history. And while the fungus on Quince leaves and fruit has always been in considerable quantity here I have never been able to find it on the Pear. A bulletin describing the results of spraying for the Pear leaf-spot in an orchard about two miles from Ithaca suggested to me that I might find the desired fungus here. The orchard was visited early in the spring in order to inspect the dead leaves in the hope of finding, not only the conidial form of the *Entomosporium* on the leaves which had been lying on the ground

during the winter, but also the perfect stage, both of which stages of the fungus I had found on Quince leaves which had been lying on the ground in an orchard during the winter. Nothing was found, however, which could in any way be considered connected with the *Entomosporium*. On the other hand, two species of the genus *Sphærella* were found on the Pear leaves, as follows, *Sphærella sentina* and *S. Pyri*.

This led me in the summer of 1895 to look more carefully for the *Entomosporium* on spotted Pear leaves. The first diseased leaves which came to my notice were on large nursery trees in the horticultural grounds of Cornell University. The older spots furnished various saprophytic fungi like *Cladosporium herbarum* and pycnidial forms of *Pleospora herbarum*, but in no case were the spores of the *Entomosporium* to be found. On the other hand, in the younger spots there was found abundantly a fungus belonging to the genus *Septoria*, a genus which furnishes many species at whose door is laid many leaf-spots of various plants. Ordinarily the spots on the Pear leaves caused by this *Septoria* would not be noticed to differ from those caused by the *Entomosporium*, but careful comparison reveals several points of difference. Many of the spots are slightly larger, and there is a great tendency for the spots to be angular and somewhat elongated in shape, while the spots of *Entomosporium* are more nearly circular. Upon the under side of the leaf at certain stages there appear minute jet-black points, which do not appear in the spots of *Entomosporium*. The microscope reveals these black points to be made up of long coiled strings of spores which have oozed out of the pycnidium of the *Septoria*. The individual spores, which are very long, slender and more or less curved or flexuous, have a light green tinge, while in mass they appear black.

Next the orchard was visited where spraying experiments had been carried on against the *Entomosporium*, and no trace of this fungus was found. But on several trees the *Septoria* was present, and in one case the tree was badly blighted, nearly every leaf being affected. Investigations were then made of several large Pear orchards at Geneva, New York, and while both the *Septoria* and *Entomosporium* were found on a great many trees, the *Septoria* was by far in the majority, and in many cases both fungi appeared on the same leaf. Material was also secured from a large number of varieties of Pear-trees in a nursery at Syracuse, and here also the *Septoria* predominated.

During June, 1896, Mr. B. M. Dugger was appointed on the staff of the Botanical Department as Cryptogamic Botanist of the experiment station here, and the investigation was placed in his charge. His observations have confirmed those of mine concerning the prevalence of the *Septoria* in the etiology of Pear leaf-spot, the *Septoria* being more abundant than the *Entomosporium*. He has been able to obtain a knowledge of a still wider range of the *Septoria* in this state, and has also received it from a number of other states. He is preparing the matter for a bulletin, and would welcome contributions of Pear leaves supposed to be affected with the *Entomosporium* from any section of the country, in order that the distribution of the two fungi may be obtained. To those who are interested I would suggest dried material now in the herbarium, the collection of Pear leaves in the early spring which have been on the ground during the winter, and freshly diseased leaves later in the season, and that these be communicated to the department here, since cultures are now in progress to determine the life history of the fungus, and it is desired to obtain and cultivate as many of the species of the genus *Sphærella* as possible, since species of *Septoria* have been in some cases connected with species of *Sphærella*.

Another important fact in connection with the *Entomosporium* has also come to light during my study of this fungus. This is the discovery in this country of the perfect fungus which Sorauer discovered in Europe in connection with *E. Mespili* on leaves of *Cotoneaster tomentosa* and *Pirus communis*.

Reference has been made above to my discovery of the perfect form on leaves of the Quince which had lain on the ground during the winter. This was in the spring of 1895, and on the same leaves were also spores of the conidial stage of the *Entomosporium maculatum*. In discussing this *Entomosporium* in the report of the Department of Agriculture (1888), Professor Scribner cites Sorauer's work on the perfect stage, and reproduces some of the figures, stating that no other observer had at that time confirmed Sorauer's discovery. Aside from the interest and importance attaching to the discovery of this form in the United States on another host, it is of interest to note that Sorauer places the fungus in the genus *Stigmatea*, which resembles *Sphærella* in the form of the perithecia and ascospores, but differs in possessing paraphyses and in the context of the perithecia. The fungus seems to me rather to belong to the *Discomycetes*, and is probably a member of the genus *Fabræa*. This genus belongs to a family of the *Discomycetes* in which the fruit body at first is closed, as in the *Pyrenomyces*, to which group *Stigmatea* belongs, but later the fruit body opens in the form of a cup, so that care is needed in observing the later stages of the fruit body to determine its true character. Also in the case of the genus *Fabræa*, when the plant is dry the margins of the cup-shaped fruit body collapse and fold together, so that it gives the appearance of the closed fruit body of the *Pyrenomyces*. On moistening the plant, however, expansion takes place, the margins part, and a broad surface formed by the exposed ends of the asci comes to view.

From the apparent wide distribution of the *Septoria* and from the very probable confusion with the *Entomosporium* in the case of some spraying experiments, it would seem that the success which has attended the efforts to combat Pear leaf-spot demonstrates by circumstantial evidence that spraying in the usual way will check the *Septoria*. In connection with nursery stock, one year's stock will sometimes be affected almost entirely with the *Entomosporium*, and another year's stock almost entirely with the *Septoria*. This suggests that in budding nursery stock or in grafting, the buds in such cases have been taken from trees affected either with the *Septoria* or *Entomosporium*; in fact, that one of the prolific causes of the appearance of the spot in nurseries may be traced to the buds which already may have the germs of the disease. If this should prove to be true, caution in the selection of budding stock, or in its disinfection before grafting, could be recommended.

Cornell University.

George F. Atkinson.

## Foreign Correspondence.

### London Letter.

*ANOIGANTHUS BREVIFLORUS*.—This south African bulbous plant, valuable for the conservatory in winter, is related to the *Sternbergias* and *Cyrtanthuses*, and is as easily managed as a Daffodil. The bulb is ovoid, two inches long; the leaves are strap-shaped, erect, about a foot long, deciduous, new ones being developed along with the flowers. These are produced in umbels on erect scapes a foot long, strong plants having ten or a dozen flowers in the umbel. They are tubular, between one and two inches long, at first erect, afterward more or less drooping, their color a bright Daffodil-yellow. In the Cape-house at Kew there are some fine examples of this plant in flower; they are mixed with a group of white-flowered *Freesias*. During the summer the *Anoiganthus* is grown in a sunny frame, and after the leaves die off in autumn they are kept dry till the flower-scapes begin to appear. They prefer a rich loamy soil, with plenty of water while in growth. The genus is monotypic. It was introduced from Natal about eight years ago.

*KNIPHOFIA PRIMULINA*.—This is a new species which Mr. Baker has described from plants now flowering in the temperate house at Kew, where it has been an attraction for the past month or so. It has the general characters of *Kniphofia Natalensis*, but the leaves are three feet long and an inch broad; the scape is three feet high, bearing a dense

raceme of flowers six inches long; the flowers are more than an inch long, tubular, the segments scarcely spreading, and the stamens are about half as long again as the tube. The color of the flowers is bright primrose-yellow. Kew is indebted to Herr Max Leichtlin for this plant, who sent it in 1894 with the information that it was from Natal and that it flowered in winter. When it first flowered it

to interference with well-established plant names except for very strong reasons. It appears that Professor Pfitzer, of Heidelberg, has thought fit to revive certain obsolete names and to divide the old genus *Cypripedium* into four. Until now we have recognized two, namely, *Cypripedium* and *Selenipedium*, the latter name being applied to all the South American representatives of the tribe. Even this

Fig. 10.—*Hoodia Gordonii*.—See page 76.

was thought to be a pale form of *K. Natalensis*. Grown in pots to flower in the greenhouse in winter it is a useful decorative plant, or it may be grown in the open ground and lifted in October, to be planted under glass.

**CYPRIPEDIUM.**—In the December number of *The Orchid Review*, Mr. Rolfe published a revision of *Cypripediæ* which is likely to meet with the disapproval of those who object

name, however, was not recognized by many, Veitch declining to adopt it in his *Manual of Orchids*. The new arrangement is as follows:

1. *Cypripedium* proper is to be limited to the terrestrial deciduous species represented by *C. spectabile*, *C. japonicum*, *C. calceolus*, etc.

2. *Paphiopedium* is the proposed name for all the Old

World species not included in 1; these are represented by *C. insigne*, *C. Stonei*, *C. niveum*, etc. These were the *Eucypripedia* of Bentham & Hooker.

3. *Selenipedium*. This name is to be limited to several South American species, none of which have ever been introduced. Examples, *S. Chica* and *S. palmifolium*.

4. *Phragmopedium* is the name proposed for all the cultivated plants hitherto known as *Selenipediums*. These are all natives of South America; examples, *P. longifolium*, *P. candatum*, *P. Schlimii*.

Whatever cultivators may think of this new arrangement, botanists, including Sir Joseph Hooker, are of opinion that it is justifiable. Apart from the question of convenience, we have the fact that 1, 2 and 4 are well differentiated in habit and behavior under cultivation. They have never been intercrossed, although seedlings have been raised from crosses between 2 and 4, but they have invariably perished before flowering.

ORCHIDS FROM SEEDS.—In my last letter I suggested that choice species and varieties of Orchids should be raised from seeds obtained artificially. I have since been informed that several Orchid breeders in this country have seedlings of such, but I am requested to withhold the names of the plants, lest it might affect the commercial value of the parents. In *The Gardeners' Chronicle* this week there is a note headed "A Scarcity of Orchids," in which attention is called to the scarcity in a wild state of various *Cattleyas* and other Orchids, due partly to the insatiability of collectors, and partly to the clearing of the land for the cultivation of Coffee. "This Coffee industry in Colombia is extending at the expense of the Orchid forests, for it happens that the Coffee region is exactly the Orchid region." Breeders have succeeded in raising from seeds a large number of species of different genera, including *Odontoglossum*, *Miltonia*, *Zygopetalum*, *Cattleya*, *Dendrobium*, *Phalaenopsis*, *Phajus*, *Cypripedium*, etc., and there does not appear to be any obstacle to the raising of many other kinds from seeds matured under cultivation. Evidently this is the direction to which we must soon perforce turn for a supply of many Orchids.

## New or Little-known Plants.

### Hoodia.

**H**OODIA is closely related to *Stapelia* and was once included in that genus. Four species are known, all natives of hot, dry regions in south Africa. They are remarkable for their many-ridged, spine-clothed fleshy stems, which are more suggestive of *Cereus* than *Stapelia*, and also for their large saucer-shaped flowers. These are colored yellowish or reddish brown and are of a disagreeable odor.

If they had not hitherto proved so difficult to keep alive under artificial treatment, *Hoodias* would certainly be now as well known in gardens as the commonest *Stapelias*. It is possible that we may yet discover how they ought to be treated so as to keep them healthy; at any rate, plants are now being tried again at Kew. The accompanying illustration (see p. 75) represents a plant flowered by Mr. Armstrong, of Port Elizabeth, to whom Kew is indebted for plants. *Hoodia Gordonii* was discovered near the Orange River more than a century ago. Fifty years later it was rediscovered by Burke, who was sent by the Earl of Derby to collect plants in south Africa, and he sent home living plants of it which were grown at Knowsley, but they do not appear to have ever flowered there. In 1874 Sir Henry Barkly, Governor of the Cape, obtained two specimens of it, one of which was sent to Kew, where it flowered in 1875, but it died the following year. A figure prepared from this plant by Fitch was published in *The Botanical Magazine*, t. 6228.

The plant has numerous stems in a cluster, suggestive of a *Cactus* in habit and appearance; they are from a foot to a foot and a half long, two inches in diameter, ridged

longitudinally, the ridges clothed with closely set yellow prickles half an inch long. The flowers are produced in clusters of two or three near the apex of the stem; they are rotate, nearly flat, four inches in diameter, the lobes short, or scarcely apparent, abruptly apiculate, yellowish brown flushed with rose, and an eye-like zone of rose surrounding the crimson corona.

A correspondent in Carnarvon, about 300 miles inland from Cape Town, writes: "It may interest you to know that *Hoodia Gordonii* is very plentiful about here. . . . It grows mostly on the slopes of dolorite-capped hills, and ought to thrive in the moist climate of England, with not more than one watering about every six months. Here it does well with a good rain in March and another in October. It also gets assistance from the heavy dews, as it generally prefers the lower side of a dolorite boulder from which the lightest rain or heavy dew would run off. I have, however, found numerous plants on a bare flat, and they appeared to thrive as well as the others."

The plant represented here is only a small one, tufts of from twelve to twenty stems being common, and these all flower together, forming a very striking object.

The other species known are *Hoodia Barklyi*, flowered in the Cape Town Botanic Garden in 1873; *H. Bainii*, flowered at Kew in 1878 and figured in *The Botanical Magazine*, t. 6348, and *H. Curreri*, which does not appear to have ever been cultivated.

## Cultural Department.

### Lachenalias.

**M**IDWINTER flowering plants are not, and never will be, too plentiful. This is the one period that taxes the skill of those who have to provide these in quantity, more especially from the end of the *Chrysanthemum* season until the coming in of Dutch bulbs in spring. *Freeseas* from the Cape of Good Hope are of comparatively recent origin in gardens and fill a place that will never again be vacant, and another valuable set of bulbs, also from the same region, are the *Lachenalias*. These are very old residents of gardens, since the records show that they were known and cultivated as long ago as 1752, and have since been continuously grown. It does not appear, however, that more than the true species were known, and these remained unimproved down to 1880. At this late date the Rev. John Nelson, an English clergyman, raised the first seedling variety, *L. Nelsoni*, still perhaps the best of all varieties. More recently still, another clergyman has entered the same field, and to Rev. T. H. Marsh we are indebted for the kinds known as *Ruby*, *Topaz*, *Little Beauty* and *Cawston Gem*, all of which are distinct gains to gardens. They are, indeed, better than the true species, with the possible exception of *L. pendula*, which is a giant of its kind.

Most of our winter-flowering plants need an amount of care and preparation during summer that adds largely to their cost, and is not always compensated for by their value when in flower. The popularity of the *Freesia* among cultivators is largely due to the ease with which it may be stored away in early summer until time for planting in autumn. The same treatment is all that is required for *Lachenalias*, so that when they are better known they should be more generally grown. Pans, such as other bulbs are grown in, or five-inch pots, should be used, owing to their dwarf habits. The pots are more desirable, owing to their adaptability for general decorative uses. We plant in August in rich soil, and place the pots in a sunny frame until it is no longer frost-proof in early winter. *Lachenalias* dislike heat and coddling, and the cooler the house, so long as it is free from frost, the better will be the flower-spikes and the foliage. The leaves are attractive and are marked like those of some of the *Dogtooth Violets*. When the pots are brought into the greenhouse they should, if possible, be placed on a shelf close to the glass, where they can get all the air possible. The flowers will be produced from November until March if a few of the best sorts are grown.

*Lachenalias* seed freely, come up quickly if the seeds are sown at once, and what is more desirable, perhaps, can be obtained true from seed. This I have heard disputed, but we have them now in bloom without the least variation from the parent variety. While some of the bulbs flower the second year, the majority will take three years to bloom. There is

still a field for the hybridist, all the more enticing that the best kinds now known in gardens are of garden origin. No one seems to have yet taken in hand the crossing of the earlier gigantic *L. pendula* with the later-flowering kinds. We this season planted a lot of *L. pendula* late in winter for the express purpose of having it in bloom with *L. Nelsoni* and *L. tricolor*, and in this we have succeeded. It only remains to cross them, and we may be able to get an infusion of bright coral-red among the yellows that has not been obtained by earlier operators.

A few notes of varieties best worth growing may be in place here, though it is preferable to procure them in autumn with the other bulbs, or as soon as they can be had from Holland. *Lachenalia pendula*, before noted, is the first to bloom. Indeed, we use it with the earliest of Roman Hyacinths, with which it is a pleasing contrast in color, while the spikes are equal in vigorous development. The leaves of this species are unspotted, and as large as those of a garden Tulip. There is a variety called *Gigantea* which we have never yet grown, but hope to next year. *L. tricolor*, of which there are at least half a dozen varieties, is also one of the best. It is in flower now in best condition, and is useful either in pots or for the flowers when cut. The stems should not be cut, but gently pulled out, as *Cyclamen* flowers are pulled. This adds length to the stem, and if it is done carefully the bulbs are not injured. *L. Nelsoni* is the best of all the sorts yet grown. Its color is a bright golden yellow; it increases readily, and is a great advance over its parents, as indeed are the other garden forms already named. It is safe to assume that if these kinds are tried they will be but a beginning, and such species as *L. aurea*, *L. orchioides*, *L. Cami* and *L. quadricolor* will be added to the set, for all are beautiful and distinct. There are many more species, some of which bear the reputation of being hard to flower in gardens, but with our bright sunny summer days to ripen the bulbs, and the longer growing season in autumn, we ought to have a great advantage over European cultivators.

When one has enough bulbs, there is no prettier way to use them than in baskets. The pendulous spikes show to great advantage in this way, and if moss, with a little bone-meal, is used to grow them in the baskets will not be heavy; a great amount of water or labor will not be necessary. The great secret of cultivating bulbous plants of whatever nature is to take as much care of the plants after they have flowered as when starting them. The bulb is built up for the next year's work after the blooming time, and on this foundation depends all the returns that will be had a year hence. We often hear complaints that *Freesias* do not bloom well if home-grown bulbs are planted. This depends wholly upon the after treatment that we give them. They should never be disturbed until all signs of growth have disappeared. All the soil should then be shaken off and the bulbs stored in a cool dry place until planting time comes again.

South Lancaster, Mass.

E. O. Orpet.

### Select Dwarf Stove Plants.

PROMINENT among these are the beautiful little *Bertolonias*. The delicate hues and exquisite markings of their foliage make them both showy and interesting and a welcome addition to any plant collection. It is somewhat difficult to bring out their true characteristics under ordinary stove treatment, as they require a more humid atmosphere than can usually be maintained, even in a small house. The additional shelter of a small frame should be provided where the atmospheric conditions will be much more easily regulated. A plentiful supply of water at the roots is necessary; syringing or sprinkling overhead is not advisable. The most convenient method of propagation is by cuttings, which strike readily in a moderately close propagating case filled with sharp clean sand. The pots should be thoroughly clean and well drained, and the compost open and porous. *Bertolonia Van Houttei*, *B. Legrelli*, *B. superba*, *B. marmorata* and *B. punctatissimum* are probably the best varieties found in general cultivation.

The genus *Sonerila* provides some beautiful species, all of dwarf growth and suited to ordinary stove culture. *Sonerila Hendersonii* and *S. margaritacea* are among the best sorts; they require moderate shade and plenty of moisture, and are easily propagated from cuttings. Rough leaf-mold with a plentiful addition of silver sand is a suitable soil for them. The red-veined *Fittonia Verschaffeltii* and its silvery-veined variety *argyrea* are the two forms most commonly grown, and are among the most easily cultivated of dwarf stove plants. They love shade and moisture and grow freely in a compost

of equal parts of fibrous loam, leaf-mold and sand. On account of their creeping habit, pans are more suitable for their cultivation than pots. Snails are particularly fond of them, and if not checked will quickly disfigure the plants.

A most attractive little plant is *Tapeionites bicolor*. The metallic dark green leaves contrast admirably with the pure white flowers; the latter are borne two or three on a stem and rise just above the foliage. *T. bicolor* thrives best in a peaty soil and is propagated most easily from cuttings. Several of the dwarf forms of *Aphelandra* may be included in this class. They are beautiful both for their flowers and foliage. The flowers are produced in terminal four-sided spikes. Usually but a few blossoms are open at one time, but a succession of blossoms continues for a considerable length of time. *Aphelandra Fascinator*, *A. pumila* and *A. Roezlii* are three of the best dwarf forms. They may be propagated either from cuttings or seeds, and some of the varieties produce seeds freely. A light fibrous soil is the best. They need plentiful watering during their growing season, but when not in active growth should be kept rather dry. They are generally cultivated in pots, but I have seen them growing and flowering admirably planted out in rock-work.

*Higginsia discolor* and *H. regalis* are two lovely dwarf plants. The former grows about six inches high, and the latter to nearly twice that height. Propagated by cuttings they are of easy culture under ordinary stove treatment. The leaves of both species are shining green on the surface and purple-tinted below, *H. discolor* being the most attractive on account of the rich, satiny gloss of the upper surface.

A neat and almost continuous flowering little plant is *Tetranema Mexicana*, commonly called the Mexican Foxglove. The flowers are borne in clusters on upright stalks about four inches high. The ground-color is purple, the markings of a light violet color. It produces seeds freely and is easily increased by this means.

Tarrytown, N. Y.

William Scott.

### Stag-horn Ferns.

OWING to the eccentric, but graceful, shapes which their leaves assume, the *Platyceriums*, or Stag-horn Ferns, as they are commonly called, are plants of prime importance for decoration, and they are specially useful in the stove and greenhouse. The species, seven or eight in number, are widely distributed over tropical and temperate countries, and all of them, with the exception of *Platycerium alcornoe* and its forms, require a fairly warm house for their perfect development. Being epiphytal in their nature, they can be grown in a variety of ways. *P. grande* can be grown satisfactorily upon large blocks of wood or upon the dead stems of Tree Ferns, which, if large enough, make ideal abiding places for this plant, and with the addition annually of a little coarse fibrous peat it can be kept in first-rate condition for many years. *P. alcornoe* also thrives in wire baskets; if it has good porous material for the roots to wander in, the entire surface and sides of the receptacle will soon be covered with foliage. For growing in pots *P. Hillii*, a recently introduced species, is the most satisfactory, as its habit is more upright than that of the others. When grown in pots it is advisable to break off part of one side and then to place the plant on that side so that the surface of the soil will not be entirely covered up with the sterile leaves, and thus make it troublesome to supply the plant with as much water as it needs. Since a considerable portion of the roots will be found layered between the bases of the sterile leaves, it is a good practice to insert between the leaves a little rough peat and moss to absorb water and hold it as long as possible. *Platyceriums* will thrive in almost any kind of open well-drained soil, but to have the foliage grow to full dimensions and give the best architectural effect the mixture must be open, so that the roots can penetrate it with perfect freedom, a condition in which they seem to delight. Sphagnum moss, fibrous peat or the coarse root masses of some of the *Osmundas*, with lumps of charcoal freely interspersed, are substances suitable for older plants. For young pieces rough leaf-mold and chopped moss answer well enough. Old plants of the species which have round sterile leaves are of such a peculiar growth that it is difficult to furnish them with a proper receptacle, but a piece of ordinary wire netting from twenty-four to thirty inches long and about twelve inches wide will answer. The ends of this should be brought together and fastened with wire in the shape of a cylinder. If one end is obstructed so that the roll when in an upright position will hold a coarse root mixture, large pieces can either be fastened to it on one side or all about it, and it can be hung up to the roof of the conservatory. *P. Hillii*, *P. alcornoe* and its variety

Majus have more or less round-shaped sterile leaves and nearly upright fertile ones. *P. grande*, *P. Willenckii* and *P. stemmaria* have very ornamental sterile fronds, especially the two former, which are beautifully divided. The fertile ones are drooping and gracefully cut. These Ferns can be propagated by sowing the spores of which old plants give a very plentiful supply, or by the root-buds which develop freely on all the species except *P. grande*.

Botanic Garden, Washington, D. C.

G. W. Oliver.

### Hardy Cyclamens.

AMONG the interesting plants which emerged from the melting snow last week were some Taurian Cyclamens with beautifully mottled leaves and brightly colored flowers. The Cyclamens have been so much improved in size of flowers and grown under glass so generally that we are apt to forget that many of the numerous species are hardy and very attractive in suitable borders. The hardiness, as in the case of many so-called hardy plants, is comparative, for they will not endure our winters except under certain precautions of planting; but if so established they are fairly reliable, and few small plants are more dainty and attractive. The first requisite to the successful cultivation of Cyclamens of all species is perfect drainage, and this must be arranged for in the borders or there is no chance for success. A good soil is an open sandy one with a trifle of peat, and the best position a raised one where they will have slight shade, possibly under deciduous trees. Limestone is said to be helpful to their growth; broken up old mortar is a good substitute, and will help provide drainage. The Cyclamens are natives of the Mediterranean region from Spain to Syria, and there is at least one African species.

Among the various species flowers may be had at all seasons of the year. *Cyclamen Coum*, *C. Ibericum*, *C. repandum* and *C. Persicum* flower in January and until May. *C. Europæum* flowers in summer. *C. Neapolitanum*, *C. Græcum*, *C. Cilicicum* and *C. Cyprium* from September to December, and *C. Africanum* in December. The flowers of *C. Græcum* and *C. Neapolitanum* appear before the leaves; in the other species they appear together. Of these, *C. Africanum*, from Algiers, is tender, but is an interesting greenhouse plant, usually having a monster corm six inches or more in diameter. *C. Persicum* is also tender, and is the parent from which all the modern large-flowered varieties of the greenhouse sorts have been evolved. These are certainly remarkable triumphs of the gardener's skill, but lately they have shown a tendency to further changes in the way of cresting and doubling which will try the temper of the botanist.

The other eight species described by Baker will probably be found hardy in gardens under conditions noted above. If a trial is attempted, perhaps *Cyclamen Coum* would be the most likely to succeed. My garden is cold, wet and clayey, and these plants do not stay long with me, yet my losses have been, I think, more from careless planting and treatment than from real difficulty in growing the plants.

Elizabeth, N. J.

J. N. Gerard.

### Propagating Chrysanthemums.

CUTTINGS of Chrysanthemums intended for specimen plants may be put in to advantage now. We have started them earlier, but, taking everything into consideration, nothing is gained unless very large plants are desired, and it is a question whether an extremely large plant is evidence of cultural skill. In any event, the feat accomplished, it is no longer considered commendable. The Massachusetts Horticultural Society has wisely, I think, lowered the size limit in pots from twelve to ten inches in diameter.

In selecting cuttings we prefer stout suckers, avoiding those found on the old stems as liable to run to bloom prematurely. No special treatment is required in rooting cuttings; any piece will grow, even a leaf, and leaf-cuttings often make very fine plants. It is the only way to fix a sport. Plenty of water and air is essential, and the mistake of giving too much warmth is the most common one. From the time the cuttings are rooted they must be kept growing steadily. It ruins them to leave them in the cutting-bed when they are once rooted, as they become hardened; such plants often come from the dealers, and they never make specimens. They can be detected at a glance. We take the soft tips and endeavor also to get them to start afresh from the root-stock. Cuttings got in this way are the only ones we can expect to succeed with. We start with four cuttings of a kind, select two to grow, and as exhibition time approaches finish the best one.

Wellesley, Mass.

T. D. Hatfield.

## Correspondence.

### Notes from Wellesley.

To the Editor of GARDEN AND FOREST:

Sir,—A day can be profitably spent in making a tour of the greenhouses in and about Wellesley in winter, although the places are seen at their best early in June, when *Rhododendrons* and *Azaleas* are in flower, or in October and early November when autumn tints light up the landscape.

In the greenhouses belonging to Wellesley College, the head-gardener, Mr. Butler, generally has something good to show visitors, although his space is somewhat limited and the structures are not of a very modern type. *Statice Halfordi*, a garden hybrid of *S. macrophylla*, was represented here ten days ago by some fine plants in full bloom. This *Statice*, although one of the most handsome decorative plants in cultivation for winter flowering in a cool greenhouse, is by no means common. *Acacia pubescens*, of which Mr. Butler has two standards, seven to eight feet high, with well-expanded heads, was flowering well. Although it has been in cultivation more than a hundred years, no plant has been found to take the place of *A. pubescens* when thickly clothed with its racemes of yellow flowers. It is to be regretted that some of our nurseries have not worked up a stock of *Acacias* in variety. No American firm catalogues them, so far as I know. In addition to *A. pubescens*, such old but beautiful sorts as *A. Drummondii*, *A. dealbata*, *A. Riceana*, *A. lineata* and others, which are probably familiar to the oldest plantmen, should have a place in every establishment where hard-wooded plants are grown. A specimen plant of *Dendrobium nobile*, which annually produces nearly a thousand blooms, was bristling with buds, and in a few weeks will be a mass of flowers. *Angræcum sesquipedale*, one of the best of winter-flowering Orchids, was showing its great ivory-white flowers, the sepals and petals spread out like rays six inches across. *Odontoglossum crispum* and *O. triumphans* were pushing up stout spikes, and *O. pulchellum majus*, a healthy little sweet-scented white species, was flowering finely. In a warm house *Phalænopsis amabilis* and the beautiful white variety, *P. grandiflora*, were in flower; the leaves of these are tough and leathery, and Mr. Butler says they never fail to flower well. They are grown in a much lighter position than is usually accorded *Phalænopsis*.

At Mr. H. H. Hunnewell's, the beautiful new *Begonia*, *Gloire de Lorraine*, a cross between *B. Socotrana* and *B. Drejei*, was covered with clear, rosy carmine flowers. This variety ought to become highly popular when it is sufficiently known; from its habit it promises to be suitable for a basket plant. This species was quite largely grown in England last summer, and it is said to bloom well out-of-doors there. No other *Begonia* bears flowers of so beautiful a color. *Streptosolon Jamesoni*, grown as a standard, was effective in one of the cool houses. Mr. Norris holds back as many Orchids as possible to flower during the *Rhododendron* season, but some good species were in bloom. *Lælia anceps* was represented in some huge baskets, the plants carrying many spikes. The white forms, *L. anceps Sanderiana* and *L. Schroederiana*, *Lælio-Cattleya Pallas* and *Cattleya Trianae*, were also in flower in the Cattleya-house. In the Orange-house the fine specimen of *Clematis indivisa*, already figured in GARDEN AND FOREST (see vol. vi., p. 167), covers a large portion of the roof, and was in beautiful flower. *Cypripedium Harrisianum* (*barbatum* × *villosum*) was represented by several good specimens. *Phalænopsis amabilis*, *P. Stuartiana*, *P. Schilleriana* and *P. grandiflora* were all in flower.

At Mrs. B. P. Cheney's beautiful place in South Natick, Mr. John Barr had a magnificent show of Cyclamens. Several hundred of these plants are grown, chiefly in eight and ten inch pots, and one side-stage about one hundred feet in length is entirely devoted to them. Others are being held back in a cold structure. The range of colors, size of flower, foliage and quantity of flowers to the plant were all that could be desired. Mr. Barr usually takes some of the leading honors for these plants at the Boston Spring Show. If he can keep his plants back this year until the third week in March they will not easily be surpassed. Roses, Carnations and all other plants on this place were clean and thrifty-looking. The early graperies were just beginning to break nicely, and the appearance of the canes gave promise of fine bunches.

A visit to Wellesley would not be complete without a call on the veteran florist, Mr. Joseph Tailby, whose compact and well-kept establishment is close to the Boston and Albany Station. Mr. Tailby's specialty, as is well known, is Carnations. Mrs. Fisher is grown largely here and surprisingly well. One large house and part of another are devoted to it. Mr. Tailby still finds it the most profitable variety of the many he

grows. William Scott is the favorite pink variety, and F. Mangold is considered the best crimson. A bed of a promising scarlet seedling, Portia  $\times$  E. G. Hill, is notable. The flower is a good clear scarlet, larger than either parent, calyx good and stem stiff. There are also some promising crimson seedlings; the old Clove was used as one of the parents, and the seedlings have a delightful clove odor. A house of Violets looked clean and healthy, Marie Louise, Lady Hume Campbell and Swanley White being the double kinds grown, and California the leading single variety. A large number of plants of Crimson Rambler Rose in seven and eight inch pots promise to be in flower by Easter, and also of the new forcing *Spiræa astilboides floribunda*; the latter is too tall and ungainly to become a popular variety.

A run on the electric cars from Wellesley brings one close to the estate of Mr. David Nevins, at South Framingham. A fine new greenhouse, 105 by 21 feet, has recently been completed here, and Mr. A. McKay already has it well filled. A bench of Violets in eight and ten inch pots makes a remarkably good showing; the plants had been brought in from a cold frame two weeks before, and they were a mass of bloom. I counted thirty-five to forty large perfect flowers hanging around the sides of some of the pots, and masses of buds were pushing up. It is not so much the quantity of the flowers as their immense size which excited surprise and admiration. The largest flowers noted were of Farquhar. This variety seems quite distinct from any other I am acquainted with, in flower, foliage and in general habit. Mr. McKay says he can easily pick out any stray plants of Farquhar among those of Marie Louise and Lady H. Campbell at the first glance. Other varieties splendidly grown are Swanley White, Marie Louise, Lady H. Campbell, California and the old Czar. Plants in cold frames were equally as thrifty here as those grown indoors. A frame of Violets here received the first prize by the Massachusetts Horticultural Society last spring in the competition for the best house or frame of Violets. A house of hybrid Perpetual Roses, planted out in solid beds, were pushing stout growths. Flowers from this house have surpassed all others at the Boston Spring Show for two seasons past. Mr. McKay has an interesting collection of Orchids, all of which looked thrifty. Some good plants of *Dendrobium nobile* (Sander's variety), *D. Wardianum* and *D. formosum giganteum* were in flower. A batch of Cauliflower, Early Erfurt, in eight-inch pots, were producing good heads ready for cutting.

Mr. William Nicholson, of Framingham, is one of the most successful all-round cultivators of Carnations in Massachusetts. Two large structures and two small ones are devoted to these plants. This season they are looking better even than in previous years, and they have always looked well heretofore. Many varieties are grown, and all were equally vigorous and were flowering freely. Eldorado, William Scott, Daybreak, Minnie Cook, Alaska, F. Mangold, Hector, Thomas Cartledge, Nicholson, Edith Foster and Della Fox were notably good; the last named is not liked as generally as Daybreak. Edith Foster, white, is popular, and Eldorado blooms as freely here as William Scott. A bench of white *Antirrhinums* suggested the value of this flower for cutting. A fine collection of flowering Begonias was an attraction here. These are specially pleasing at this season. A house, 100 by 15 feet, filled with Tomatoes planted after Chrysanthemums were cut, was setting a heavy crop, Eclipse being the kind most largely grown.

Taunton, Mass.

W. N. Craig.

## Recent Publications.

*The Forcing Book.* By L. H. Bailey. Macmillan Co., New York.

Ten years ago one could find forced Radishes, Lettuce and occasionally Cauliflower in small quantities in the New York winter markets, but there was nothing like a regular supply of them, and, indeed, there was hardly any demand for them. The business of growing vegetables under glass has since then developed more rapidly than any other branch of horticulture in this country, and this little manual, which belongs to the useful Garden Craft Series, has been prepared to set forth the principles and explain the details of its practice. Since plants in glass houses are entirely under artificial conditions their cultivation demands special skill and the most watchful care. Novices therefore need instruction from the beginning, and Professor Bailey, who has given personal attention to experiments in growing

vegetables in connection with his horticultural work in the University and in the experiment station, has qualified himself as a teacher by making practical tests of various methods. The work properly begins with a brief treatise on the construction and management of forcing-houses, for, since the grower must make his own climate as well as his soil, it is quite as essential that he should be able at will to create and command these conditions as it is that he should know exactly what the conditions are which each crop needs. The discussion of the various forms of houses, with their structural details, is very complete, although concise, and for the space it takes it gives more valuable information than can be found elsewhere in the same compass. All such practical questions as would be treated under the head of soil, fertilizers, irrigation, shading, pollination, etc., have received careful study, and the beginner can feel safe in following them to the letter. The book is written primarily for those who intend to take up the winter growing of vegetables as a business, but there are few gardeners with a glass house at command who can resist the challenge to try their skill at raising a melon for Christmas dessert, and few persons who do not enjoy the occasional luxury of a dish of fresh asparagus or tomatoes out of season.

The book is thoroughly up to date, and contains not only a selection of the most approved varieties of each crop for forcing in this country, but it presents the results of the most recent studies in cultural practice and summarizes the results of such instructive investigations as those of Professor Galloway in reference to the mechanical properties of soil essential to the production of the best Lettuce; Professor Munson's experiments in pollinating Tomatoes at the Maine Station; the Connecticut experiments with chemical fertilizers in artificial soil; the tests with electric light in Cornell, West Virginia and elsewhere; Green's plan of subirrigation, or watering by means of underground tiles, and many other practices and processes which have been explained from time to time in this journal.

The manual makes a handy volume of 260 pages, helpfully illustrated and carefully indexed.

## Notes.

*Lilium auratum* is grown to its highest perfection by Mr. G. F. Wilson at his home near Weybridge, Surrey, England. A single stem sometimes carries as many as sixty flowers in a great pyramid whose summit is six and a half feet high.

Since October 1st 622,324 barrels of domestic potatoes have passed through the New York market, somewhat more than two-thirds the quantity handled in the corresponding period a year ago. The receipts of the home crop during last week amounted to 31,314 barrels, besides 1,800 sacks from Great Britain, 200 sacks from Germany and 566 barrels from Bermuda and the West Indies.

The Board of Trade of California, following the example of the Royal Horticultural Society of England and similar associations in various countries, has appointed a subcommittee to promote the International Horticultural Exhibition in Hamburg, which is to continue from May until October of the present year with one continuous show, and special exhibitions for plants and flowers at the time of their best season.

The immense quantities of fruits consumed in New York city, and forwarded from this centre to other sections of the country, are suggested in the arrival last week on a brig from Porto Cortez of 91,000 cocoanuts. Although this fruit, even in its manufactured form, is but occasionally used in families, and then in small quantities, 1,687,500 cocoanuts have arrived at this port since the first of the year.

The plant, often called the Water Hyacinth, *Pontederia crassipes*, has been naturalized in some of the rivers of our south Atlantic and Gulf states, and has increased so rapidly that it covers the surface of the water for great distances. In the St. John's River, Florida, and in some of the canals about New Orleans it is difficult for steamers to work their way through this raft of vegetation, and when they do the plants close in behind the boat and occupy the surface completely as before. The obstruction to navigation has become so serious that an

appropriation of \$10,000 was made last week by the Senate of the United States to enable the Secretary of War to study means of freeing our watercourses from this nuisance.

Steam has shortened the time of ocean transit to such a degree that the perishable fruit on street-stands of almost any city in the world may have come from a remote part of another continent. Good peaches from South Africa are now on sale in the London markets and command \$2.50 for a box containing twenty. The first installment of the apple crop from Tasmania will reach London about April 20th, and shipments will arrive regularly every week until July. About 100,000 cases are expected.

Mr. C. L. Allen has a good word to say for the old Madagascar Periwinkle as one of the most pleasing of plants which can be used for bedding, since it can be had covered from June until frost with flowers which are admirably set off by glossy green foliage. If seeds are sown now they will produce plants that will be of flowering size in June, and the seedlings will come true to the type of flower, whether pure white, rose-colored, or white with a crimson eye. If the old plants are taken up at the approach of frost and stored in boxes of sand in a warm cellar and left so dry that growth will not be encouraged they will keep well, and if the stems are cut back at the approach of warm weather they will make much stronger plants the next season and will flower earlier than those grown from seed.

The North Carolina Experiment Station has had prepared a bulletin entitled "The Home Vegetable Garden," by Professor F. W. Massey, to which a short supplement on Pests of the Garden has been added by Gerald McCarthy, the botanist of the station. Altogether, this little bulletin makes up a pamphlet of some fifty pages, which is an excellent handbook for the cultivation of vegetables for home use, not only for the latitude of North Carolina, but for a large part of the country. Besides giving a selection of the different varieties of plants, the book contains some first-rate rules for the best methods of selecting, laying out and enclosing a garden, of making and using cold frames and hot-beds, of preparing and enriching the soil and much other information which a novice ought to be grateful to have placed within his reach.

Mabel Morrison is a Rose that is not often forced, but a few blooms of it in the window of William H. Brower & Sons, on Broadway, near Twenty-third Street, a few days ago showed to good advantage among other brighter blossoms. It lacks the substance of Baroness Rothschild, from which it is a sport, and it is not so full as the flower of the parent plant, but for this very reason it is more delicate, and its pure or flesh-white cup-shaped flowers have a peculiar grace. The foliage is a singularly bright and cheerful green. In the same window was a specimen *Acacia cultriformis*. Its spikes of flowers, near the end of the branches, stand out in large numbers, making a thyrse-like mass of deep yellow in beautiful contrast with the silvery foliage. These glaucous leaves along the stem resemble scales, and are set on in the peculiar edgewise fashion which gives the plant a marked appearance.

Mr. George H. Hazzard, Commissioner of the Interstate Park of the Dalles of the St. Croix, has submitted his first report to the Governor, and with it a pamphlet of a hundred pages containing much useful matter about this most interesting state reservation. When the park is extended so as to include the lower Dalles, as it in all probability will be, it will extend along three and a half miles of shore-line on the St. Croix. The tract is unique in the variety of its geological features, rich in forms of plant-life, and its scenery is remarkable for wild and picturesque features. In speaking of the advantages of public recreation-grounds for people in the country as well as in the city, the Superintendent states that a Grange in Ohio has recently bought a tract of woodland on the banks of a beautiful stream for a park, while a few miles above The Dalles, on Wolf Creek, the farmers have bought a fine grove where they have erected some shelters and other conveniences for holding Fourth of July celebrations, harvest homes and picnics.

Glacé fruits are among the most attractive and satisfactory of the varied offerings of first class fruit stores. They come from France in paper boxes, each containing a quarter, a half, or a full pound of inviting preparations, and also in one, two, four and six pound wooden boxes. Some of the larger packages are filled with only one kind of fruit, but these and the smaller ones, with assorted fruits neatly arranged in rows of one kind, are beautiful and make easy buyers of inspecting customers. A two-pound box, for exam-

ple, holds nearly four dozen fruits in seven rows separated by dainty white lace paper. There are small white pears, tiny limes, alternating yellow and green, large apricots, deep and rich in color, green gages, a showy line of rose-colored pears, one of delicious-looking figs, and by way of novelty and variety, English walnuts, thickly encased in a candied covering. Other combinations are made from meaty cherries, with sweet Bigarreau and the sour fruit to choose from, some arranged with straw stems for convenient handling; peaches, fresh-looking slices of pineapple, some white and others a wholesome rose-color from being dipped in natural fruit-syrup; red and white strawberries; melons, the seeds removed and the whole form retained; mirabelles, small yellow plums; young green almonds, prepared with the outer and inner shell, the kernel being hardly formed, and slices of oranges. The colors, which are very distinct, make striking contrasts. These colors are always the natural tints of the fruits themselves, or in some instances of the bright juices of other fruits. Limes, which come green and yellow, are the unripe and the ripened fruits. The prices range from fifty to eighty cents a pound. Turkish fig-paste—some white and some pink—is a generally esteemed fruit confection, and apricot paste is more rarely seen. In another class are the candied orange, lemon and Sicily citron, seen in grocers' stocks, and glacé Angelique, or stalks of rhubarb, which are used in confectionery. For several years past a high grade of glacé fruits from California have been sold in eastern cities, including figs, plums, cherries and other sorts. Crystallized ginger is, perhaps, the best known of all these confections, and Brazil nuts and other imported and native nuts are largely used in candied coverings, while fruit bars are popular. Among the most costly delicacies are candied rose petals at \$1.50 and violets at \$2.50 a pound. Many of the fruits also come crystallized, or with an additional coating of granules of sugar.

As we go to press the announcement is made that President Cleveland has set apart by proclamation thirteen new forest reserves, including altogether an area of more than twenty-one million acres. This, added to the reservations previously established by Presidents Harrison and Cleveland, increases the total area of reserved forest land in the western states and territories to about thirty-nine million acres—that is, the combined area of these reservations, exclusive of the National Parks, is as great as that of the states of Maine, New Hampshire, Vermont, Massachusetts and Rhode Island. The new reserves include all the central portion of the Black Hills of South Dakota, the Big Horn Mountain Range in Wyoming, the Jackson Lake country south of the Yellowstone National Park in Wyoming, all the Rocky Mountains of northern Montana, a valuable forest region in northern Idaho, the principal part of the Bitter Root Mountain region in Montana and Idaho, the Cascade Mountains of northern and of southern Washington, the Olympic Mountain region in north-western Washington, the Sierra summits of California north of the Yosemite National Park, the San Jacinto Mountains in southern California, and the Uintah Mountains in northern Utah. The location and boundaries of these forestlands have been carefully studied by the commission appointed by the National Academy of Sciences, who have made it their aim to include as much as possible of the great bodies of timber that are left on unentered land, and wherever it was practicable to secure the continued existence of the forests on high mountain slopes which protect the sources of streams most useful for irrigation and navigation. Much remains to be done before this magnificent domain is rendered safe from spoliation, but the simple act of setting these forest lands apart is enough to justify the creation of the commission. In our next issue we shall publish with some fullness of detail a description of the reservations, and we only add here that it may be doubted whether any act of President Cleveland's administration will have such a beneficent and far-reaching influence upon the welfare of the country as this series of proclamations. The country is to be congratulated on having a Chief Magistrate who is capable of taking such a broad and statesmanlike view, and the people will be grateful to him for the promptness and decision with which he has acted.

The New Forest Reserves.

WE announced in our last week's issue that President Cleveland had signalized the close of his administration by taking an important step toward solving the difficulties of forest preservation on the public domain of the United States. On the 22d of February he added thirteen new reserves to those already established, so that, exclusive of the national parks, the forest reservations in our western states and territories, taken together, will now cover an area sixty miles wide and more than one thousand miles in length. To the general summary we have already published regarding the location of these priceless tracts, we now add a more detailed description of each reserve.

The Black Hills reserve has an estimated area of 967,680 acres. The mountains are here covered with forests of Yellow Pine, and in the valleys between them Spruces and Cottonwoods principally occupy the ground. Special value is attached to these forests, as they contain the only timber which is produced in the territory between Minnesota on the east and the Big Horn Mountains of Wyoming and the Rocky Mountains on the west. They supply the material for a number of important mines and afford the only local timber and fuel supply for the settlers residing in the valleys of streams flowing from these mountains. The whole Black Hill region has suffered seriously from fire and the illegal cutting of timber, and for years the mines in this region have been practically supplied with timber and fuel taken without authority from the public domain.

The Big Horn reserve has an estimated area of 1,193,080 acres, and embraces both slopes of this high, isolated and exceedingly broken range of mountains, which contains a number of peaks varying from 9,000 to 11,000 feet in altitude, and the sources of many streams needed for irrigation. The forests here are composed of Pines and Spruces of small size; they contain, however, material to supply the local demands of agriculture and mining, although timber probably will never be shipped from them. They are most valuable in the protection they afford the sources of streams capable of irrigating a large territory which, without irrigation, can produce only scant and uncertain pasturage.

These Big Horn forests have already suffered severely from fire, and unless they can be protected the irrigating capacity of the Big Horn streams and the value of many of the valleys of central Wyoming for agriculture will be destroyed.

The Teton Forest Reserve embraces 929,448 acres, and is south of and adjacent to the Yellowstone Park Timberland Reserve. The forests which cover it are similar in character to those in the Yellowstone National Park, and, although they have no great commercial value, are capable of supplying any local demands that will probably ever be made on them. This reserve contains the Teton range of mountains, Jackson Lake and some of the grandest and most picturesque scenery of the Rocky Mountains. Many streams flow from this reserve, and as a reservoir of moisture it is of great value. Here, too, is a favorite home of the elk and other large game, and as a game preserve it will well supplement the Yellowstone National Park and the Yellowstone Park Timberland Reserve previously established.

Two reserves are made in northern Montana; the first, the Flat Head Reserve, embraces both slopes of the main Rocky Mountain range or continental divide, and extends from a point near the line of the Great Northern Railroad northward to the international boundary. It has an estimated area of 1,382,400 acres, and contains within its boundaries several high glacier-covered peaks, numerous lakes, the sources of important streams, and, perhaps, the most sublime mountain scenery in the United States. That part of this reserve which lies east of the continental divide holds the sources of many tributaries of the Missouri and of the Saskatchewan, dependent entirely for their water on the snow which falls on these mountains, and is protected by their forests of Pine and Spruce. In this reserve west of the continental divide are the great north fork of Flat Head River and many smaller tributaries of that stream. The forests here, under the influence of a more humid climate, are heavier than those on the eastern slopes of the continental divide, and are composed of Spruces, Firs, Tamaracks, Cedars and Cottonwoods, which often grow to a large size, and which in time can be made valuable in the development of Montana and its industries.

The second reserve in northern Montana extends southward from the line of the Great Northern Railroad nearly to the forty-seventh degree of north latitude, and has an estimated area of 2,926,080 acres. It embraces an exceedingly rough mountainous territory watered east of the continental divide by the north fork of Sun River and west of the divide by the south fork of the Flat Head River and by Swan River, a large tributary of Flat Head Lake. The forests in their general features and value resemble those in the Flat Head Reserve. It contains no agricultural or grazing land and no evidence of valuable mineral deposits, and no entries of land have been made within its borders. The forests on this reserve are valuable east of the continental divide for protecting the supply of water in certain important tributaries of the Missouri; west of the continental divide for the great stores of timber which they contain.

The Priest River Reserve occupies the basin of Priest Lake and Priest River, in the extreme northern part of Idaho and north-eastern Washington, and extends from a point a few miles north of the Great Northern Railroad to the international boundary, covering the basins of all the streams flowing into Priest Lake and Priest River. It has an estimated area of 645,120 acres, and is clothed with what is believed to be the most valuable body of timber in the interior of the continent. This is largely composed of the western White Pine, *Pinus monticola*, which grows here to its largest size and greatest perfection, Tamarack, Cedar and Spruce, all of large size. This reserve has been made in order that this body of timber may be preserved until it is actually needed by the country and that the Government may obtain from it its true market value.

The Bitter Root Forest Reserve includes a forest region of extremely precipitous and rugged mountains on both sides of the boundary between Montana and Idaho, and covers an estimated area of 4,147,200 acres, being the largest of all the new reserves. East of the summit of the Bitter Root Mountains it contains the sources of all the western tributaries of the Bitter Root River, which waters the broad valley of that name and finally falls into the Columbia. West of the summits of the Bitter Root Mountains the reserve includes some of the tributaries of the Clearwater River and many of the tributaries of Salmon River; it protects, therefore, the sources of streams which can be used advantageously for purposes of irrigation, while the whole is clothed with forests of Yellow Pine, Lodge Pole Pine, Spruce, Fir and Cedar. The forests in this reserve have often suffered from serious fires, many of them probably more than a century old, but no lumbering has been done west of the Bitter Root Mountains, and the whole region is rough and broken. It has no value for grazing except over a few small scattered areas, and no considerable deposits of valuable minerals. The forests in this reserve will be able to supply a large amount of material to the inhabitants of eastern Oregon and Washington, which is now one of the richest wheat-producing regions of the United States, and to the people of treeless southern Idaho. This reserve is probably the largest unsettled region in the United States, there being within its boundaries but three quarter sections of land entered in Idaho, while no land has been entered in Montana. Few persons pass over its rough and difficult trail, and it can, therefore, be easily protected from fire.

The Washington Forest Reserve extends in Washington from about the one hundred and twentieth degree of west longitude to nearly the one hundred and twenty-second degree, and from the International Boundary southward to a little below the forty-eighth degree of latitude. It extends over both slopes of the Cascade Mountains, and is broken and entirely clothed with forests. Within this reserve, east of the Cascade summits, are the sources of large rivers, important for the irrigation of a region which needs only water to become exceptionally fertile. West of the Cascade summits are some of the heaviest forests on the continent composed of Spruces, Firs, Pines, Cedars and Hemlocks of the first commercial value. Mount Baker, the most northern of the large volcanic peaks of Washington, is situated in the western part of the reserve; it contains 3,594,240 acres.

The Olympic Forest Reserve occupies the high and broken Olympic Mountain region in north-western Washington and contains an estimated area of 2,188,800 acres. This is a country of steep and rugged mountains, their highest peaks clothed with glaciers and with perpetual snow. The forests here are watered by more copious rains than fall in any other part of the United States, and are composed of enormous Spruces, Firs and Cedars. In productiveness the Olympic forests are surpassed in the world only by the Redwood forests of California. Few explorers have penetrated far into this region, which from the denseness of the vegetation offers exceptional difficulties to travel, and there is no record that it has been crossed in a north and south direction. This reserve is believed to contain the largest and most valuable body of timber belonging to the nation; and in no other part of the United States can the forest, uninjured by fire or the axe, be seen over great areas in all its primeval glory. There is no agricultural or grazing land whatever in this reserve, and no indications of precious metals have been found in it. Its forests can be made to yield permanently great quantities of timber, and its wildness, the picturesqueness of its surface and its remoteness make it one of the most valuable of all the forest reserves.

The Mount Ranier Forest Reserve is an enlargement of the old Pacific Forest Reserve, which is now carried southward along both slopes of the Cascade Mountains nearly

to the Columbia River, and is made to include a narrow strip west of the original reserve in order to include some of the chief glaciers of Mount Ranier. The name, too, is changed to that of the great mountain which is the chief natural feature of this reserve. The southern extension of this reserve protects the sources of many of the tributaries of the Yakima River, which furnishes the water for an important irrigating plant, and it will also preserve a vast amount of timber of first-rate commercial value.

The Stanislaus Forest Reserve contains 691,200 acres and lies along the summits of the Sierra Nevada Mountains in California, immediately north of the Yosemite National Park, which it joins. Many streams flowing east and west head in this territory and are fed by numerous small lakes and alpine meadows. The forests, except in a few townships, are scattered and without value beyond their influence on the flow of springs and streams. This region has long suffered from the illegal pasturing of sheep and by the fires which always follow the shepherd through the forests on the public domain, and, unless its natural features can be preserved, its value as a water-storage basin will be seriously impaired.

The San Jacinto Forest Reserve embraces the San Jacinto Mountains in southern California and contains an area of 737,280 acres. This is an arid region, the lower slopes of the mountains being clothed only with a bushy chapparal growth. Scanty forests of stunted conifers, however, exist on the sides of some of the cañons facing the ocean and cover the high valleys and elevated slopes, and the preservation of these forests will maintain the supply of water needed to irrigate the valleys of south-western California. These valleys before water is poured on them are deserts, but with the aid of water they can be covered with prolific orchards.

The Uintah Forest Reserve embraces most of the Uintah Mountain Range in northern Utah, and contains valuable forests of Spruce which protect the sources of several large streams, several of which are already utilized for irrigation. The region within the reserve is uninhabited, but there is already a large agricultural population living in the territory immediately adjacent to it, and this population will suffer for water and for a local timber-supply if the fires which have now for many years swept through these forests are allowed to destroy them.

The establishment of these reserves is the first achievement of the Commission of the National Academy appointed last year by Professor Wolcott Gibbs, the President of the Academy, at the request of Secretary Hoke Smith. The Commission during the past summer has examined the general features of the territory now reserved, and the requirements, present and future, of the people living near these forests; it has laid down their boundaries, and it is upon its recommendation that they have been made. The creation of such a Commission appears, therefore, to have been justified; its duties, however, are by no means completed, and it now remains for it to prepare a scheme by which the thirty-nine million acres of mountain forests can be protected from illegal inroad, and can be profitably managed for the benefit of the whole people of the United States. Under existing laws no one can legally enter the reserves, obtain from them any forest supplies, or carry on mining operations within their borders. Such a state of things, of course, cannot be allowed to exist, and, unless these forests can be made to play the part which national forests play in all other civilized countries, the reserves must sooner or later be given up and their forests allowed to perish by unrestrained pasturage, fire and unwise cutting. Great as is the service already performed by the National Academy through this Commission, the task still left to it in organizing a permanent forest service and securing its adoption by Congress is infinitely greater and more difficult.

IN an act which has just passed both Houses of Congress it is provided that any person who shall willfully set fire to any timber, brush or grass on the public domain, or shall allow such fire to burn unattended near inflammable material, shall be guilty of misdemeanor under the laws of the United States, for which he can be fined not more than \$5,000 or be imprisoned for not more than two years, upon conviction in the local district court of the United States. Section 2 provides that all persons who build camp-fires or any other fires near timber or other inflammable material on the public domain shall totally extinguish them before they break camp, and the failure to do this will also be a misdemeanor subject to fine or imprisonment, or both, upon conviction in a court of the United States. With a view to encourage prosecution under this act it is provided that the fines collected shall be paid into the Public School Fund of the county where the offense is committed. It is not probable that this law will at once be enforced with any great rigor or vigor, but it is an admirable thing to have on the statute book, for as public opinion becomes educated, and especially as the people in the neighborhood of our great western forests begin to appreciate their value as they ought, this law will have behind it an energy of popular approval which will effectually enforce it. When the great Teak forests of India first came under the control of the British Government every one felt at liberty to despoil and burn them, but now the people who live in these forests are their staunchest defenders, and there is no doubt that a few years hence the people who visit our great western forests as tourists for pleasure, and the people who spend their lives near them, will all unite in cherishing them as among the most useful and beautiful of our national possessions.

#### The Chemise World.—II.

MANY northerly slopes in the Chemise region would be in open woods but for the recurring brush fires. It is a repetition of the conditions in the prairie states, where the grass fires kept trees from getting out of the scrub state. Nearly all the bushes in the Chemise region have great vitality and sprout vigorously after each burning. Sometimes a longer period than usual elapses between fires, and the heavy brush on the north hillsides has time to go through the thinning process. First, the Chemise, then the *Ceanothus* die out, and the weaker sprouts give up the battle. The next fire finds an open wood of low trees with insufficient fuel to make a fire to scald the bark of the vigorous saplings, but it clears the débris and makes them safe for the future. Douglas Spruce may come in, and Maples. The soil is strong, and moisture enough is present, and the trees attain a good size. On ranges where fires are kept out, this procession from chapparal to small timber is going on rapidly. Conifers are not so fortunate in the battle. Douglas Spruce is found throughout the Chemise region in scattering trees or small groves, usually on rugged hillsides close to watercourses. The thin bark of young trees of the Douglas Spruce makes it as susceptible to fire as the Pines, and the few now living are survivors. On large trees the bark is thick. These sometimes withstand many conflagrations, but at last succumb to an unusually hot fire, and, falling, expose their neighbors, until the little grove is wiped out. Nature has always kept these great slopes well clothed with a variety of trees. In twenty years, with a moderate chance, much of the brush land would be covered with timber of constantly increasing value. The white man is not the only offender, and the Indian for many years had fired the brush periodically.

The problem of the future forester is simple here; he need only keep out the fires, and a forest would soon be established. The soil is richer, in many places covered with heavy brush, than in the present woodland. The thinner growth on poor lands was spared by fire, while the rank growth on rich lands invited the flames. Species

which in some localities develop into grand trees, in others are found in the form of low brush. This is accounted for in some instances by poverty of soil; in others, aridity or altitudes are the causes. But, in nine cases out of ten, the dense copse is formed of sprouts from great charred stumps. These have ample vitality, if left alone, to send the sprouts up into trees, and with nature's thinning they would make stately specimens. The young trees, not so slender as when growing in a dense forest, reach upward for the light, and are well clothed and symmetrical.

*Castanopsis chrysophylla*, the Chestnut Oak or Western Chinquapin, is often found in dense copses in the higher portion of the range east of Ukiah. In the Chemise region it is seldom over five feet in height and fruits at that size. The burr is not unlike that of the eastern Chestnut, the nut small and thick-shelled. Just across the valley to the west it again occurs in the dense chapparal growth, and between the periodical brush fires reaches a height of from twenty to forty feet. It is, however, in the Redwood region that it is to be seen at its best. On the high ridges in the Redwoods it often grows from eighty to one hundred and twenty-five feet high, straight as a Pine, and branchless for two-thirds its height, with a magnificent full head. Such a monarch of the woods stands near the public road a few miles above Willets, in this county, and was visited and described by that pioneer botanist, the late Dr. Kellogg, who considered it the king of its kind. The name *chrysophylla* is due to the yellow powder underneath the leaves. In a breeze the leaves alternately present a dark green and golden side with a beautiful effect. The Chestnut Oak follows the Coast Range from Monterey into Oregon.

Another tree which is common in a shrubby form in the high Chemise region is the California Live Oak, *Quercus chrysolepis*. I will reserve for a future time a description of it as it grows at its best. It is common as a large bush or low tree on the north hillsides, while on some gravelly hill-slopes it forms a dense low growth. All of these shrubby or low-growing forms have leaves as green and prickly as an English Holly, while on old trees the leaves are entire.

*Quercus Douglasii* is common in the Chemise region in the drier places. The California Black Oak, *Q. Californica*, is, however, the most widely distributed tree in this region. Little clumps of it are seen everywhere, and on all shaded hillsides its beautiful green foliage is conspicuous; many groves of it have reached the size where they are in less danger from fire. The common Scrub Oak here is *Q. dumosa*, var. *bullata*, which seldom exceeds twenty feet in height. *Madroña*, too, is common, but does not often reach the fruiting stage. *Madroña*, *Arbutus Menziesii*, has a very smooth, glossy brown bark, which is shed annually. This tree grows rapidly and sprouts freely, but naturally suffers more from fire than almost any other tree.

Ukiah, Calif.

Carl Purdy.

#### The Arrangement of Flowers.—I.

##### SHORT-STEMMED FLOWERS.

THE many short-stemmed flowers in our gardens are difficult to arrange satisfactorily for decoration. After many efforts I began to use small and shallow dishes, and flower arrangements became a new pleasure and delight. In six small crescent-shaped glass dishes known years ago as "bone" plates, a layer of wet spongy moss is placed, and they are filled with water. In an early morning visit to the garden I gather into a large, round, flat basket, that probably was originally some Japanese farmer's shade, great velvety pansies that need to be picked to keep the plants blooming through the summer. The plants in one bed of Sweet Alyssum, *Alyssum maritimum*, flower so low that the little, thick, white heads are hardly three inches high, and these I cut off close to the ground. These little stemless flowers have an unpromising look, but the saucers and moss provide a suitable setting. If the dining-table is long the dishes are placed end to end the

length of the table, making an irregular rope effect. Sometimes I commence at the centre to arrange the pansies, and all the dark blue and purple flowers are selected. These are placed in the moss, some high, others low, some turning one way and some another, the outside of the little crescent relieved by the Sweet Alyssum, and so on down the length of the table, with lighter pansies in the next dish, and still lighter ones beyond, until the lavender and pale yellow and white pansies finish the ends of the rope of flowers. Generally, flowers that bloom in different colors, as the Corn-flower, *Centaurea Cyanus*, are more effective when the colors are separated and one or two shades only are arranged together, but I think pansies are an exception, and all their colors seem to harmonize. Nevertheless, the effect is much heightened by tasteful combination. A careful study of the way the pansies look on the plants will help to avoid any stiff effect in their arrangement, and the combination with Sweet Alyssum makes a beautiful table decoration. Heliotrope may be used with pansies, or Maiden-hair Fern, or small clippings of their own bright green leaves, always avoiding a regular arrangement of first a flower and then a leaf. Nearly half of a dish may be solidly filled with Maiden-hair, and the eye turns with delight from the mass of quiet green to the gorgeous coloring of the pansies. An especially fine blossom should be prominently displayed or surrounded with colors that best bring out its beauty.

These same dishes lend themselves to many other pleasing effects. I sometimes place them point to point to form a circle, and in the centre a tall slender vase with a few white roses or other flowers of quiet coloring that do not spoil the effect of the pansies. For a large table an ample platter of flowers may be arranged in the centre, and the small dishes extended down the table from it; or one low dish filled with moss and flowers and edged with Ferns or some different flower is effective. The pronounced pansy clusters may be softened with the foliage of the common garden Carrot, the delicate leaves falling around the edge of the platter like a lovely ruffle of lace. If the flowers are watered each day they will keep fresh for a long time.

Besides the crescent saucers a number of other low dishes may be easily procured, such as cheap pressed glass olive and bonbon dishes, all shallow enough to be filled with moss, and the shapes are often quite artistic. Soup dishes, fish platters and bread plates were frequently pressed into this service until the housekeeper maintained her rights in the pantry, and I have been forced to get the pressed glass. After all, there is nothing more satisfactory than glass for flowers; it requires extra care, but a package of washing powder will keep it looking bright with little trouble.

If desirable moss does not grow as near a garden as it does to mine it may readily be had from a florist, and it can be kept moist in a tin box, and the same moss used several times. Pansies have been suggested as the principal example of short-stemmed flowers, but many others will show to the best advantage arranged in this way, as the sweetbrier rose, the fragrant cinnamon rose, forget-me-nots, violets and nasturtiums.

### London Letter.

THE annual general meeting of the Royal Horticultural Society was held at Westminster on February 9th. A large number of Fellows were present, and the proceedings were of an unusually smooth and satisfactory character. The President, Sir Trevor Lawrence, called attention to the amount of useful work done by the Society during the year, and to the absence of evidences of dissatisfaction among Fellows and friends of the Society. The balance-sheet showed that about four thousand pounds now stand to the credit of the Society, a state of things which proved the wisdom of the new departure made ten years ago when

the Society, at that time deeply in debt, quitted South Kensington and decided to devote itself to horticulture exclusively, instead of combining it with brass bands, fireworks and tea-gardens.

The experimental gardens at Chiswick are being gradually remodeled and the keep and collections of the Society's garden made worthy of the headquarters of English horticulture. Dr. Masters expressed a hope that efforts would be made to keep Chiswick to the fore by holding now and then exhibitions or formal meetings of some kind to bring the Fellows and friends of the Society there. Professor Michael Forster remarked that the Society had not got to the extent of its usefulness and there is a strong feeling in some quarters that good experimental work done on scientific lines might be undertaken at Chiswick with beneficial results to horticulture. The Society must have a garden, and, moreover, one that will always do creditable work in the interests of scientific horticulture. The annual cost of these gardens to the Society is about £2,000. Mr. Barron's successor, Mr. Wright, was accorded high praise by the President for the work he had done since he took charge at Chiswick.

The bimonthly meetings and exhibitions held in the hall continue to attract large numbers of those interested in horticulture, owing to the fact that every plant with any pretensions to rarity or exceptional beauty, and even examples of cultural skill, is sent to these meetings for certificate or commendation. During last year eighty-four first-class certificates were awarded, principally to plants, and three hundred and fifty awards of merit. The Council consider this number excessive and recommend that the committees should be more careful in selecting. There is no good reason for granting certificates to old favorites, as is sometimes done now, solely on the ground that they have never had such recognition, otherwise I do not remember that any plant distinguished by a certificate last year was unworthy of it. Sixty cultural commendations were voted to plants showing extra cultural skill, over half of these being Orchids.

It has been felt that the record of the plants certificated was incomplete without an accurate drawing or picture representing the essential characters of each. To remedy this defect a move has been initiated by the Orchid Committee, certain members of which undertake to pay a third of the expense, by which all the Orchids certificated will in future have their portraits painted by a competent artist. A suggestion was made that this should be done for all plants certificated, and it is probable that this will soon follow, should the pictures of the Orchids prove a success. As a rule our horticultural journals are energetic in preparing and publishing drawings of all meritorious new plants exhibited, but these are not always of such a character as to enable one to make critical comparisons. After all, *The Botanical Magazine* has been and continues to be the portrait gallery of all good and interesting species of plants introduced into cultivation, and it is only the varieties and forms of garden origin for which some similar arrangement now requires to be made. Competent pictures of these will have a value to the student of racial development among garden plants now and in the future, a subject of quite exceptional interest to botanists at the present time.

In January, 1893, the Council published a list of all the plants, flowers, fruits and vegetables certificated from the year 1859 to 1892. A supplement is now ready, bringing the list down to December, 1896. Each part is issued at the price of one shilling, but the two together may be obtained for eighteenpence, at the Society's office.

An examination in the principles and practice of horticulture was held on May 1st, concurrently in different parts of the United Kingdom, a centre being established wherever a magistrate, or clergyman, or schoolmaster, or other responsible person accustomed to examinations would consent to superintend one on the Society's behalf and in accordance with the rules laid down for its conduct. No limit as to the age, position, or previous

training of the candidates was imposed, and the examination was open to both sexes. One hundred and fifty-two candidates presented themselves for examination. The names and addresses of those who succeeded in satisfying the examiners, together with the number of marks assigned

English history. Some of these proposals were for one reason or another found to be impracticable, others were found to involve a far larger expenditure of money than the Society can command or could reasonably hope in so short a period to collect. They have, therefore, after most

Fig. 11.—*Pyrus occidentalis*.—See page 86.

1. A flowering branch, natural size. 2. Vertical section of a flower, enlarged. 3. A fruiting branch, natural size. 4. Cross-section of a fruit, enlarged.

to each, will be found in the Society's *Journal*, vol. xx., part 1, 1896, page 58.

The Council have had before them various proposals for celebrating the attainment, by Her Most Gracious Majesty the Queen, patron of the Society, of the longest reign in

careful consideration decided, with Her Majesty's gracious permission, (1) to strike a special medal or medallion, to be called the Victoria Medal of Horticulture, and to be awarded honoris causa in the domain of horticulture. They will also (2) join in the celebration of the event which is to

take place at the great show to be held at Shrewsbury in August, to which they have received a very cordial invitation.

This novel proposal was passed over without comment at the meeting, but there are indications of uneasiness as to how these medals will be distributed so as to avoid creating ill-feeling.

A proposal to institute an "arbor day" in the interests of the cider industry was submitted to the meeting, but met with no encouragement, the feeling being that the subject belonged rather to the domain of agriculture. At the same time there is much to be said in favor of a united effort to renovate our orchards by the removal of old worthless varieties of fruit-trees, particularly Apples, and substituting better sorts. There are thousands of acres occupied with trees that cannot be of the slightest value in these days of an easy supply of good fruit from foreign sources. There is a difficulty, however, in the fact that many of the proprietors of these "wasted orchards" are too poor to afford the cost of renovation. During last month nearly £300,000 worth of apples were imported into England. The first installment of peaches from the Cape last week, and 100,000 cases of apples, are announced to arrive from Tasmania in April and May next.

There is always an interesting display of plants at this meeting, and that of last Tuesday was particularly so. Orchids were numerous, and among them were several new hybrids of distinct merit, namely, *Lælio-Cattleya violetta*, a hybrid between *L. purpurata* and *C. Gaskelliana* (Veitch); *Phalænopsis Hebe*, a hybrid between *P. rosea* and *P. Sanderiana* (Veitch); *Phajo-Calanthe Brandtiae*, a hybrid between *P. Assamicus* and *C. Veitchii* (Sander); *Cypripedium Enid*, a hybrid between *C. bellatulum* and *C. Spicerianum* (W. Rothschild); *C. Rolfei*, said to be a hybrid between *C. bellatulum* and *C. Rothschildianum*, but considered by the committee to be between the former and *C. insigne* (Statter); *Dendrobium Burberryanum*, a hybrid between *D. Dominianum* and *D. Findlayanum* (J. Chamberlain). There were also some magnificent specimens of *Dendrobium* from Messrs. Cypher, of Cheltenham, and a beautiful example of the rare *D. subclausum*, with bright orange-scarlet flowers, was shown by Messrs. Veitch.

London.

W. Watson.

## New or Little-known Plants.

### *Pyrus occidentalis*.

THIS little alpine Mountain Ash is the best marked of the whole group in the deep blue-green color of its leaves and its dwarf habit, as I had good opportunity to observe last summer in a journey which carried me through many of the forest regions of the western states and territories, where I met with this shrub in Washington, near the summit of the Cascade Mountains at the point where they are crossed by the line of the Great Northern Railway at an altitude of 3,400 feet, near the timber-line of Mount Ranier at 6,000 feet altitude, at 5,000 feet altitude at the timber-line on the ridge south of the Solduc River in the Olympic Mountain region, and in Oregon near the timber-line on the north slope of Mount Hood.

*Pyrus occidentalis* (see illustration on page 85 of this issue) where I have seen it is a shrub with many stems from eighteen inches to two and a half feet high, forming broad, symmetrical compact clumps, and during their first season puberulous or even hirsute, and with large, broadly ovate pubescent winter buds. The leaves vary from two inches to nearly eight inches in length, with slender hairy stems, and three, four or five pairs of lateral leaflets; these are short-stalked, oblong-elliptical or oblong-obovate, entire below, serrate only toward the rounded apex with a few coarse mucronate teeth; they are from one to two inches in length and from one-third of an inch to nearly an inch in width, deep blue-green on both surfaces, but deeper on the upper surface than on the lower. In the early autumn

the leaves turn bright scarlet. The flower-clusters are from one inch to two inches across, and the expanded flowers are about a quarter of an inch in diameter; they are quite glabrous, with the exception of a few short hairs on the acute, nearly triangular calyx-lobes, and of the conspicuous masses of long, slender white hairs which cover the ovary. The fruit is subglobose, rarely more than a quarter of an inch long and bright orange-red, with short and comparatively broad seeds narrowed at the ends, and nearly semicircular in outline.

At the high altitudes\* where I have only seen this plant, it remains buried in snow until the beginning of August, and then, as the snow melts, bursts suddenly into full vegetation. So short here is the period of growth that the side of one of these shrubs when it is growing against a cliff may have flowered and begun to set its fruit while the branches on the other side, owing to their covering of snow, are still leafless.

Sereno Watson, who first distinguished *Pyrus occidentalis*,† refers to it the shrubby Mountain Ash of the high California Sierras, but this plant differs from the Cascade shrub in its greater height and more open, tree-like habit, in its glabrous branches, buds and leaves, in its dark green, not blue-green, leaflets, which are serrate below the middle, and frequently nearly to the base, and in its larger flowers and fruit and proportionately much narrower seeds. Although this Sierra plant differs from other forms of the second species of Mountain Ash of western America in its shorter leaflets, it is probably only an alpine form of that widely dispersed and very variable plant which has always been referred to *Pyrus sambucifolia* of Kamchatka, but is evidently quite distinct from that species.

I was fortunate in obtaining a few ripe seeds of *Pyrus occidentalis*, and these have been planted in the Arnold Arboretum and distributed among a few European gardens in the hope that this pretty and distinct shrub may be added to the list of garden plants.

C. S. S.

## Cultural Department.

### Daffodils for Pot Culture.

IT is strange, since bulbous plants are so generally used for forcing, that the Daffodils, the best of them all, should be almost utterly neglected as subjects for pot culture. It is true that within recent years the old double yellow Daffodil, which the trade calls Von Sion, has become popular, and is forced in quantities for the cut-flower market, but it is only a poor representative of the varied beauty, both of form and color, displayed by this wonderful family. This old double form is distinctly a plebeian strain and lacks the general grace of the family, and, as yet, I find that there are not a few intelligent persons who are acquainted with no other Daffodil. Hyacinths and Tulips are flowered in pots in every greenhouse, and perhaps the only reason why Daffodils are not used in this way is that we get into ruts and, apart from the old double Von Sion, we leave Daffodils alone with a possible exception in the case of the overwhelmingly odorous Jonquils or the Paper-white Tazetta forms. Daffodils are more often forced in England than they are here, but there is a stronger reason for growing them in pots in this country. In an average English season the Tenby Daffodil begins to show flowers in the third week of February in the open ground, and thenceforward throughout the long and gradually opening spring a succession of Daffodils can be maintained until the Poet's Narcissus fades in June. In this country, as a rule, no flowers of any size break through the frosty ground before March is more than half gone, and last year it was mid-April before the spring flowers were awakened, and then the sudden appearance of August weather soon dried them up. There is, therefore, much more reason in this country for protracting the spring flower season than there is in England, and for this the Daffodils are the very best pot-plants that can be used, for by making selections from different sections of this large family we can have a season which lasts through months.

\* Specimens of a plant which appears identical with *Pyrus occidentalis* were collected by Funston in 1892 on the shores of Disenchantment Bay, Alaska, and this species may be expected to range southward along the coast mountains of British Columbia.

† Watson, *Proc. Am. Acad.*, xxiii., 263 (excl. hab. Cal.) (1888).

Taking the Trumpet Daffodils first, we had in January Henry Irving and Golden Spur in flower, the first one a bold, rich yellow, shaped like the Tenby Daffodil, but altogether larger; the other larger still, but lighter in shade and exquisitely beautiful in form. Following these came Maximus, which is now out of flower, the richest in color of them all, magnificent in proportions, with its trumpet finely frilled. Emperor is now opening and Horsfieldii will follow it soon, and both these are of regal beauty and show to the very best of advantage in pots. Horsfieldii is well known as among the noblest of the bicolor group, with its pure white perianth and yellow crown. Then come the Star Daffodils with their tiny chalices in the centre of broad, spreading saucer. This large and variable section of the family is now represented by the lovely Barri conspicuus, its corona fringed with a margin of deep orange-red. A score of forms slightly varying from this type can be had, and every one of them is good. Mrs. Langtry is now in flower, the type of another section, the Albino, with flowers like a Eucharis in miniature. This variety, or the Duchess of Brabant, the Duchess of Westminster, Catherine Spurrel and one or two more once tried will never thereafter be neglected. The well-known Poet's type is another section, and the early kind known as Poeticus ornatus has already been in bloom, after which the later varieties will maintain the succession.

In short, there are a hundred varieties good enough and distinct enough to grow and flower in pots, and their cultivation is of the very simplest. Pot them up, four, five, six or more bulbs in a pot, according to size, during August or September, and stand them in any convenient spot. They need not necessarily be kept covered nor darkened, as they will fill the pots with roots in any case. Place the lot which is to flower first in a temperature of fifty-five to sixty degrees early in December and they will open during January, while by moving other batches in succession the display may be kept up for three or four months, and it never need be monotonous if a wise selection is made and every batch consists of a different variety. Last, but not least, after they have flowered the bulbs need not be wasted. By preserving their foliage they may be ripened off and planted outside in beds, borders or shrubby groups, or in the grass, and naturalized if one has the room. Further, those who have to study economy in their purchases may use their bulbs for forcing again by giving them one season's rest, growing them in the open ground, so that with two lots of bulbs, one in pots and another outside, alternating, there is actually no need to make annual purchases, and, in fact, one's own stock will be found to increase considerably as time goes on.

Madison, N. J.

A. Herrington.

[Flowers of Emperor, Sir Watkin, Barri conspicuus and Mrs. Langtry, which accompanied these notes, were admirably grown.—Ed.]

### *Nægelia cinabarina.*

GOOD flowers are always appreciated in the winter, and it is especially pleasant to meet a plant or group of plants that one was accustomed to see and grow in early years, but which have been lost to sight from various causes since. An agreeable experience of this kind occurred to me a few days ago when I entered a greenhouse and unexpectedly saw in full bloom a mass of this old *Nægelia*, known forty years ago as *Gesneria*. These were vigorous specimen plants in five-inch pots, about two feet high, with large cordate leaves and fine racemes of superbly colored flowers. The leaves of this variety are beautifully shaded with flame-colored hairs, giving them a velvety lustre, while the flowers, like small, drooping Gloxinias, are vermilion, with yellow throat irregularly marked with scarlet at the base of the limb, and borne in racemes.

*Nægelias* are exceedingly ornamental plants on account of their free-flowering qualities and also their beautifully marked foliage. For general decorative purposes, a pot-grown plant eighteen inches to two feet high, the foliage covered with a bright nap and numerous spikes of brilliant flowers, makes a unique table decoration. They ought always to be grown in quantity, however, so that the leaves can be cut for decorative combination with the flowers of *Allamanda*, for example, when they produce splendid effects. Although rarely seen now, *Nægelias* are of easy culture. One reason why they have fallen into obscurity is the general use, or misuse, of the garden hose. They are moisture-loving plants, as other *Gesneriaceæ* are, but they resent having their leaves constantly wet. As the water-supply is too often from wells or the hydrant, it contains lime or other mineral matter in solution, and the sediment left among the minute hairs on the leaves

after frequent waterings gives them a rusty appearance, or at least, their brilliancy is gone, they are more or less stunted, and good flowers need not be expected. To maintain healthy and vigorous stock the plants must be fully developed, or they will get weaker and ultimately perish. Great care must be taken to preserve the foliage, and if water is known to contain lime, etc., the plants should not be watered overhead or syringed with it.

*Nægelia* plants may be had in bloom in succession, or at any desired period of the year. The stolons should be potted at different times from January to July in a soil of fibrous loam, peat and leaf-mold in equal parts, with a due proportion of sharp sand. The soil should not be sifted, but rubbed through a coarse screen to separate any rough pieces of roots, stones, etc. The pots should be clean and thoroughly drained. Any size may be used as may suit individual needs. The stolons may also be started in pots or seed-pans, using fine soil, and afterward be potted off singly, selecting the strongest plants for single pots and setting others three in a pot. These should be placed in a temperature of seventy-five degrees and watered sparingly until after growth has started. They should be near the glass to prevent "drawing," but need shading from the sun at all times. A warm, moist atmosphere is essential, and a dry air or a cutting wind is disastrous to them. In summer a batch may be grown in a frame or pit on a bed of cinder ashes, if properly shaded and ventilated, and when well established they should receive an occasional watering of weak liquid-manure. Plants in flower may be kept in a cool house, and an atmosphere not too humid at a temperature of sixty-five to seventy degrees, which will preserve and prolong the flowers in good condition. After the plants have finished flowering they should be preserved in a natural state until the leaves die down. Less water will be required at the roots, and in summer-time the plants may be placed in a frame outdoors, but must be kept shaded from the sun. When they have completed their growth they can be gradually dried off and the pots with their contents placed under the bench of a stove or other suitable place and kept dry, but care should be taken that they do not lie near the heating pipes, or the stolons will dry and shrivel up. The temperature should range between fifty-five and sixty degrees. In this condition they may remain until needed or until the time arrives for starting another lot. They can be propagated by increase of the stolons, or by cuttings of the shoots from mature leaves or seed. The leaves may be divided into sections or used whole as those of *Gloxinias* are treated, and if in the proper condition will at any time form stolons for the following season. The seed may be sown in same manner as *Gloxinia*.

Few, if any, insects affect these plants. As they start afresh in new soil and clean pots they make clean headway unless carelessly handled. Never introduce them into houses where thrips or mealy bug exist. Thrips will attack the plants and are troublesome to get rid of, as fumigating will be necessary, and this injures the plants. If mealy bug attacks them the safest remedy is clean water applied in a small stream very carefully from the hose until dislodged. A sure cure for mealy bug, and the least injury to the most delicate and tender foliage, is wood alcohol diluted with water. Take a small quantity in an ordinary cup and with a camel-hair pencil or small piece of sponge on the end of a stick for a holder dip in the alcohol and apply direct to the insect without wetting the entire plant. No brushing or rubbing is necessary, for this would be injurious. After the application the plants may be syringed carefully with soft or rain water. If this can be used during the growing season so much the better, as the plants are helped by occasional syringings with absolutely clean water without any lime in solution.

Riverton, N. J.

W. Tricker.

### Greenhouse Work.

BY the beginning of February the sunshine becomes stronger and some shading should be provided for foliage plants. A variety of materials may be used, and in a large establishment this necessity involves a considerable expense. For a limited area of glass, especially on a private place where the greenhouses are often divided into a number of small compartments for different purposes, roller shades of thin cotton cloth, burlaps, or wooden slats are most satisfactory, and are especially useful on Orchid-houses, where at times it is desirable to give full light. On large greenhouses or where several houses are built together in a block it is not always practicable to use roller shades, and then the glass is usually painted on the outside. Lime-wash is the cheapest material for this purpose, but it is easily worn off by heavy spring rains; it also eats off the paint from the woodwork and injures the putty.

For a very light shading a mixture consisting of one pint of boiled linseed oil to one gallon of turpentine is quite satisfactory; it is easily applied with a large brush and withstands the weather. Naphtha and white lead, or kerosene and white lead, in proportions to suit, are used for this purpose on many large commercial places; these make a good shading in summer, but they do not withstand frost and snow. Linseed oil should never be mixed with this preparation unless a permanent paint is desired on the glass. Another preparation useful for shading is a cold-water paint known as Indurine; this withstands the weather much better than the lime-wash, and apparently does little injury to woodwork.

At this season the value of a slightly heated frame or pit is particularly evident, as much young stock is in preparation for outdoor planting to follow the crop of spring bulbous flowers. Such a frame need not be costly, and will do much to relieve the congested condition of the greenhouses and to obviate the use of unsightly shelves in them.

Young Carnations, Geraniums, Verbenas, Drummond Phlox and other annuals make a more sturdy growth in frames, and will be in better condition for planting out-of-doors.

Cuttings of Carnations may yet be put in, and a surplus of these plants in autumn will allow of more critical selection when the blooming stock is brought in again. Planting out the rooted cuttings of Carnations in flats or shallow boxes filled with good soil is not a new method, but it is a good one; it not only allows of their ready removal from one house to another, but the plants are less liable to become starved than those in small pots. Rose cuttings may also be made now, and if properly cared for will root quickly. Grafting the ordinary Tea Roses, such as are used for forcing, has again been discussed by some expert growers, and the opinion has been advanced that it is a paying operation. To say the least, it is interesting work, and even in the line of experiment it is worth a trial. The stock most highly recommended for this purpose is Manetti, and the experiment may be made now.

Mention was recently made of the sowing of Gloxinia seeds (see GARDEN AND FOREST, vol. x., page 27). When the seedlings are large enough they should be pricked out into small pots and shifted on into a larger size as soon as the roots come through the soil nicely, for if they are once stunted they do not soon recover. These plants require light rich soil, a rather moist atmosphere and moderate shade. Similar conditions apply to Tydasas, Achimenes and Eucodonia.

The best time for repotting Ferns is when the growth begins, and the young roots thus get the benefit of the new soil. Much of the old soil is removed in repotting, and the ball is much reduced. A reasonable after-treatment includes care in watering to avoid any extreme, and also a closer atmosphere until the growth is renewed.

### The Forests of Pennsylvania.

To the Editor of GARDEN AND FOREST:

SIR,—The state of Pennsylvania has attacked the forestry problem so seriously that I wish to invite attention to one or two points in the Report of the Commission which was editorially reviewed in your paper, vol. ix., page 521. It is a matter of some regret that Dr. Rothrock has not given more detailed information as to actual forest areas in the state and their condition, especially since the Commission covered into the state treasury more than \$5,000 of the sum appropriated to its use. It would seem that this money could not have been put to better or more legitimate use than in furnishing more accurate data on these points. Dr. Rothrock tells us that the present method of making forest area returns by the assessors is unpardonably bad, and yet this seems about the only source of information on this important topic of which he avails himself. The fire areas and the damage caused thereby was gained by circulars of inquiry from which the recorded returns are meagre and unsatisfactory. Nevertheless, the Report, as you have stated, is rich not only in fact but in suggestion, and is a notable addition to the popular literature of forestry, for it is the evident intention of Dr. Rothrock to enlist public interest not only in forest preservation but in all that pertains to trees.

It appears that 36.29 per cent. of the state area is in timber, but no estimate can be made of the value of this forest cover. "Much of what appears as timber land is not such in any productive sense. It may be producing Scrub Oak of no value or White Oak of great value." In Lackawanna and adjoining counties there "is an unproductive area of 970 square

miles which may be regarded more as a menace to the prosperity of the commonwealth than as an element of strength." So recently was this waste a lumber-producing area that in 1894 Dr. Rothrock counted thirty-six solid White Pine stumps still standing on an acre of ground. To-day, however, Yellow Pine from the south is being imported into the region for home construction. There is no development of mineral wealth, and the only possible function of the area is the production of timber, but it is a literal barren over which fires sweep every year, destroying the young growth and rendering the soil more and more sterile. Other regions of similar character are noted, and the forest crop removed thence is discussed, showing a constantly decreasing value in the timber output of the state, with a corresponding increase in waste areas. The figures quoted show conclusively that the White Pine, the most valuable of Pennsylvania trees, is practically exhausted. There have floated through the Williamsport boom, for the years mentioned, Pine and Hemlock logs as follows:

In 1875,	190,000,000 feet, b. m.,	. . .	White Pine.
" "	19,963,736 "	" "	Hemlock.
" 1884,	154,000,000 "	" "	White Pine.
" "	84,980,514 "	" "	Hemlock.
" 1893,	33,197,267 "	" "	White Pine.
" "	186,984,478 "	" "	Hemlock.

Dr. Rothrock is careful to explain that the increasing amounts of Hemlock do not indicate an inexhaustible supply, but, on the contrary, Hemlock too is approaching extinction.

The reduced value of the forest area is further illustrated by the lands advertised for tax sale, the amount being for 1894 1,500,000 acres. The Commission concludes that "between lands stripped of timber and worthless, and worn-out and unprofitable farm lands, Pennsylvania has at this hour not less than 8,716 square miles (about one-fifth the total area of the state) which have ceased to be an element of strength, and that this area is passing constantly into a worse condition." The state possesses practically no public lands, but the Commission, in discussing available areas for forest reserves, opposes the plan of using lands advertised for taxes, since their isolation renders their management too expensive, aside from the small size of such tracts.

The chapter on Timber and Fire as elements in the forestry problem is illustrated with a view of a volunteer crop of White Pine, thirty-five years old, standing in "The Barrens" of Center County, and this is conclusive evidence of the ability of this species to reproduce itself when protected from fire. As Dr. Rothrock well says, "planting alone goes for nothing in the absence of protection."

An examination of the final chapter of the Report, in which details regarding the forest area are given by counties, emphasizes the regret that the facts relating to this part of the Commission's work are so few. Nevertheless, data enough are given to show urgent need of a complete forest survey of the state, a work which will doubtless be undertaken in due time and for which Dr. Rothrock is peculiarly fitted.

Washington, D. C.

Charles A. Keffer.

### The Keeping Qualities of Fruits.

To the Editor of GARDEN AND FOREST:

SIR,—One of my boyhood recollections is of a long-keeping apple which grew in an old orchard. There was an abundance of these apples in our cellar long after all the other varieties had disappeared. It was due to the fact that they were so sour not even a boy would eat them as long as any others remained. This variety was a beautiful-looking apple, very highly colored, of good size; the skin was thin, yet very firm and rather tough; the flesh was very white, tender and juicy, and if it had not been so decidedly acid the variety would have been a valuable one. A fruit must have something more than its keeping qualities to recommend it, otherwise it is soon consigned to oblivion.

It is one of the difficult problems of the fruit growers in the states south of Mason and Dixon's line to secure long-keeping varieties of apples adapted to the locality. It is a well-known fact that the late winter varieties of the north when grown in the south become autumn varieties. The Baldwin, for instance, when grown in the south matures early in autumn and will keep but a short time. It has often been said that Delaware is not adapted to apple-culture, but the fact that many varieties of fine apples are grown there is rapidly changing that opinion. It is very true that even northern-grown varieties are difficult to keep in prime condition in that climate. Never-

theless, there are several good long-keeping varieties which appear to be specially adapted to that locality.

The Jackson apple is a variety regarded very highly for its keeping qualities throughout the state. The tree is a prolific bearer, the fruit is of good size, the color is a dark purplish red on a green background. The skin is sufficiently tough and thick to make it a most excellent variety for handling. The color of the flesh is greenish white, and when in its prime, late in the season, it is tender, juicy and of excellent quality. The Lily of Kent, a native seedling, is an excellent variety with good keeping qualities. It is not as yet extensively disseminated in the state, but is rapidly growing in popularity. The old Winesap is a good keeper and bears very heavy crops. It is one of the best grown in Delaware. Stayman's Winesap bids fair to be valuable. In keeping qualities, productiveness and flavor it is superior to Winesap. The Roxbury Russet is a favorite variety in nearly all sections of the country on account of its good keeping qualities, and the Northern Spy, if carefully handled, can be had in its prime throughout March and April.

The keeping qualities of apples would be greatly enhanced if they were gathered as soon as fully grown and stored in a cool place. It is the custom with many fruit growers in Delaware to allow the apples to remain, without gathering, until a buyer is found for the crop, which is often long after the fruit should have been picked and stored. Recent experiments in spraying fruit give evidence that the keeping qualities are greatly improved by the use of fungicides.

Throughout Delaware the Kieffer pear is very largely grown, as it is one of the most profitable varieties. It is an excellent keeper, is a heavy bearer and makes a fine appearance. These pears are grown mostly for canning. When eaten out of hand they have little flavor, yet they sell well, and are among the most profitable of market fruits.

The firmness of the flesh of the strawberry greatly enhances its keeping qualities, but it must be firm throughout, and especially so on its surface. Those varieties whose seeds are prominent are usually the ones that will keep best. The flesh of the Bubach is rather soft upon the surface, although it is quite firm otherwise, and it does not stand shipping as well as many other varieties.

### College Instruction in Horticulture.

To the Editor of GARDEN AND FOREST:

Sir,—Professor Munson, in closing his very interesting article on "An Outline of a Course in Horticulture," on page 3 of your current volume, invited discussion of the subject. I have since been waiting for some one whose sufficient experience gave him the right to present some positive statement of what a college course in horticulture ought to be. For myself, I confess I have not yet made up my mind, and I should like to venture that a respectable representation of my collaborators are still giving their courses tentatively. Nevertheless, what experience I have had gives me some opinions which differ from those of Professor Munson, and these I submit for what they are worth.

Horticulture is advanced work, considered beside the average college study. It involves a considerable amount of elementary physics, chemistry, and especially botany. Besides this, the facts and principles of horticulture are not so clear cut and self-evident as in the sciences mentioned, and their discrimination requires a higher grade of student ability. For this reason horticulture ought not to begin before the junior year. It seems to me to be a mistake to require more than three courses in horticulture of undergraduates. As many elections may be offered as circumstances indicate, but more than three required courses in this subject cannot be given without crowding out something else which is of more importance for the symmetrical development of the average student than any fourth course in horticulture. If electives are provided, the students who have a taste for plant study may take as much time in horticulture as they can spare from the general required course. Some strong institutions in this country are giving less than three courses. I think two required courses are better than four, but the two should be strong, and anything less would be quite inadequate.

If three courses are required, I prefer the following arrangement: (1) Propagation and pruning. These subjects are closely related, and they come first because of their intimate association with the elements of plant physiology, which should be given in a preceding course in botany. (2) Pomology, which should be made to include small fruits, grape-growing, etc. (3) The modifications of plants under culture. This includes

plant-breeding, theories and applications of evolution, laws and limits of distribution, and the critical discussion of such general physiological problems as fruitfulness, hardiness, etc.

In the first course I have always used Professor Bailey's *Nursery Book* as a text-book. A text-book has many advantages over instruction by lectures, especially with beginners, and, contrary to my preference expressed above, I have always been compelled to begin horticultural instruction with sophomores. In general pomology we are absolutely without a text-book. Barry's *Fruit Garden*, Thomas' *Fruit Culturist* and others are valuable guides and reference books, but there is nothing which has the systematic arrangement and which constantly refers facts to principles as a text-book should. In studying the amelioration of plants, we have Professor Bailey's *Plant Breeding* and his more extensive *Survival of the Unlike*. I have used the former, and am now using the latter. Of course, any instructor who is capable of administering such a course at all will not be satisfied with these for text-books, but he will find either a great assistance to pupils. He can then present his own notions and develop other related subjects as his judgment suggests.

Constant personal contact with growing plants is one of the most essential considerations in the study of horticulture. The effectiveness of this part of the course depends chiefly on the unfailing ingenuity of the instructor. In some colleges the general machinery of instruction and discipline makes this comparatively easy. In other institutions the instructor has the power of precedent and habit against him. It makes comparatively small difference what general plan is adopted if the one condition is secured—constant personal contact with growing plants. Of course, that plan which keeps the student most constantly and keenly on the watch for information from the plants in hand is likely to be the best. For this reason I prefer to assign special original problems to individuals or to small sections of two or three students, rather than to require just so many hours of manual labor. It is extremely hard to prevent slinking by lazy students and lagging by dull ones in work of this kind, but it is worth the effort. Elective courses may be given in landscape-gardening, forestry, vegetable-gardening, floriculture, forcing-house management or other subjects, depending entirely on facilities and demands.

In conclusion I would like to add my invitation to that of Professor Munson for a wider discussion of this subject.

University of Vermont.

### Recent Publications.

*The American Fruit Culturist.* By John J. Thomas. Twentieth edition, revised and enlarged. By Wm. H. S. Wood. New York: William Wood & Co.

The first edition of this work was published a third of a century ago, and that it has kept on reappearing in constantly revised editions is a proof of its standard value. It contains, according to its subtitle, practical instructions for propagating and cultivating all the various fruits adapted to the United States, and this edition contains chapters on nuts and on wild fruits, subjects which have not before appeared, while the chapter on subtropical fruits has been carefully prepared by Mr. E. H. Hart, of Federal Point, Florida, who writes instructively and with commendable fullness on the cultivation of the Orange, the Lemon, the Citron, the Shaddock, the Lime, the Banana, the Date, the Fig, the Pineapple, the Guava, the Loquat, the Persimmon and the Pomegranate. In reference to all these tropical and wild fruits, as well as the more common domestic fruits, great care has been used in describing and figuring the different varieties of the most approved newer sorts, as well as those of recognized standard value, while the final descriptive list and index remains a most useful compilation, preserving the record of the older varieties which are superseded but kept in the lists as a matter of pomological history. The chapter on insects and diseases is brief, but it contains the best recent information regarding the more common pests, and Professor Bailey has summed up the matter with a compact little treatise on the spraying of fruits for insects and for fungous diseases. It is needless to say that this practice, which is now considered indispensable by every fruit grower, was not heard of when Mr. Thomas wrote the book originally, and that this most important step forward in the management of fruit

plantations is treated with comprehensive intelligence. Of course, the opening chapters on Propagation, Pruning, the Management of Nurseries, and all the other details of fruit-growing are given as they were in the last edition, but after all the value of the book is in its descriptions and figures of the different fruits and in the careful way in which these have been arranged.

Altogether, this remains the best manual of fruit-culture which we have in America, when considered as a cyclopedic account of different species and varieties. But while it is the best of its kind, we may as well say that there is room for a book of another kind—one devoted not so strictly to the varieties of trees as to the discussion of the principles which ought to underlie the entire practice of fruit-growing and the treatment of fruit-lands and fruit-trees. We can hardly have both of these in one book, and it seems that the time is about ripe for the appearance of some treatise which takes a more comprehensive and profound view of the scientific side of fruit-culture. What is needed now is fundamental knowledge rather than rules, and we shall give cordial welcome to a book written on such lines, especially if it is as thoroughly well done in this direction as this last edition of *The American Fruit Culturist* is in its own peculiar field.

### Notes.

The first importations of the new-crop Brazil nuts arrived here from Para a week ago, consisting of 1,200 bags.

A Texas authority on Pecan-culture says that the nuts should invariably be planted with the sharp points upward and about six inches below the surface.

Apples and pears from the United States and Canada have been selling in Vienna this winter, probably the first time they have appeared there in any considerable quantities.

Messrs. Peter Henderson & Co., of this city, celebrate the fiftieth anniversary of the founding of the firm by an edition of their large quarto catalogue on fine heavy paper. It makes a book of 170 pages, containing a full descriptive list of standard and novel plants and seeds and "everything for the garden."

Mr. J. H. Hale stated at the last meeting of the Connecticut Pomologists that recent experiments tend to show that steam is of much greater value than either smoke or artificial heat in protecting orchards from spring frosts. If fires are prepared at a distance of fifty feet apart and kept lightly covered with wet hay or some other material which will hold water all the time and yet not put out the fire, a fog-like vapor will cover the field and modify the temperature so that the orchard will escape when the air about the field is much below the freezing point. Of course, this remedy will not work if there is much wind.

Dried and evaporated fruits for cooking purposes include among domestic sorts blackberries, huckleberries, red and black raspberries, cherries and plums, pitted and containing the seeds, sliced and quartered apples, showy apricots and pears in halves, large silver prunes, the regular dark prunes and raisins. While many of these dried fruits come from California, not a few are from New York and some of the Atlantic coast southern states. Evaporated peaches, for example, are known in the trade as peeled and unpeeled California yellow, peeled fancy Delaware and peeled fancy North Carolina sliced. In addition, currants are imported from Greece, raisins from Spain, prunes and prunelles from France and the cheaper prunes from Turkey, besides Corsican citron and other Italian fruit-peels.

At a late meeting of the Vermont Botanical Club, Mr. Cyrus G. Pringle read a most entertaining paper on "Reminiscences of Botanical Rambles in Vermont." Professor Brainerd alluded to Mr. Pringle's researches throughout the length and breadth of North America, and said that perhaps no living man had seen and recognized as many flowering plants in their homes as he. But, with this wonderful experience in fields which opened before him wider prospects every year, it is very evident that Mr. Pringle has never enjoyed any collecting more thoroughly than he did while searching among the lofty mountains, lonely lakes and unbroken forests of northern New England in his early days. The *Burlington Free Press* has published his paper in full and it makes two columns of fresh and delightful reading.

The current issue of *The Garden* gives a colored plate of *Erythronium Johnsoni*, a comparatively new Dogtooth Violet, which is a native of the Coast Ranges of southern Oregon. The flower is a decided shade of red or red-pink, which is deepest on the outside of the petals, and which is a novel color in this genus. The flowers were shown for the first time in England last year, where they were much admired. The scape grows nearly a foot high, so that when established this will make a handsome plant, and English gardeners are congratulating themselves over a new acquisition among hardy plants. We should be pleased to learn something of the behavior of this plant from any of our readers who are interested in early spring-flowering bulbs and who have tested this one in our eastern states.

A car-load of California fruit donated by growers to the Armenia Relief Committee of this city was sold at auction last Friday. Oranges realized from \$1.35 to \$.70, and grape-fruit from \$.90 to \$21.00 a box, the entire lot netting above \$1,000. Choice Navel oranges, from California, sell in the regular wholesale markets at \$.50, and the best California seedlings cost the retail dealer \$.35 a box. All oranges have been advancing in price during the past fortnight, and desirable sizes of Valencias were last week worth \$.35 by the case, while Sicily oranges brought \$.25. Since the first of the year 64,890 boxes of oranges and 156,970 boxes of lemons have been received here from Sicily alone. Limited quantities of new oranges of the second crop are being received from Jamaica, and bright and russet Florida oranges are still in market, together with Tangerines and Mandarins from the same state.

Mr. Martin Benson writes to *American Gardening* that the Papaw, *Carica Papaya*, makes a most interesting feature in a group of tropical plants, with Bananas and other plants with leaves of the largest size. The Papaw belongs to the Passion Flower family, and has a spongy stem and a crown of broad, long-stalked palmate leaves. Mr. Benson shows the picture of a male plant which was ten feet high, with a tuft of leaves six feet in diameter, and it was planted out in May from a six-inch pot. The largest leaf was three feet across, with bone-white midribs and thousands of small yellow deliciously fragrant flowers in racemes three or four feet long appearing at the base of every leaf. A female plant bore nine fruits. These trees ultimately reach a height of twenty feet. Mr. Benson does not explain how many years they can be kept and transplanted into an open border and back again into a greenhouse. The growth which these plants made, however, seems to be equal to that which is made under ordinary tropical conditions.

Many packages of vegetables which arrived here from Florida last week were refused by the consignees on account of poor condition, and were left on the docks to be sold by the transportation companies for what they would bring toward paying expenses for carriage. The damage was caused by heavy rains followed by extremely hot weather. Cabbage, cauliflower, beets in bunches and string-beans suffered most, and the scarcity of really high-class vegetables has raised the price for the best grades. New beets are now coming from Charleston, South Carolina, and the first asparagus and new potatoes came from the same section last week. Good tomatoes come from Key West and from Cuba in large quantities, and in smaller lots from the Bahamas. Lettuce and other salad plants are being received from New Orleans, but the high cost of transportation by rail limits shipments from that locality. Rhubarb from Michigan is now in our markets. Besides onions from Canada, Spain, Bermuda and Cuba, some are now being imported from France and from Egypt.

It is an old device to plant Lima Beans, Melons, or other tender vegetables in inverted sods, but it is more often talked about than actually practiced. A correspondent of *The Country Gentleman* cuts the close-cropped turf of a rich pasture to fit in a strawberry basket, and in the loosened and enriched soil he plants the seeds some six weeks before the weather is permanently warm. He inures the plants to their outdoor conditions by setting them in a shallow trench two weeks before the time for final transplanting, with a rim of boards around it high enough to give the plants head-room, and around this rim is banked the soil taken from the trench. A tight board covering at night will protect them from frost, and this may be left off when there is no probability of freezing. When the weather is settled the toughened plants can be set out without disturbing their roots and they will keep on growing with no check whatever. Instead of watering the surface of the ground the flat box of plants may be set in a shallow tank of water until the soil is saturated, and in this way the washing and baking of the surface is avoided.

## Quarantine Against Destructive Insects and Plant Diseases.

NOT long ago a correspondent in Denver wrote that a considerable portion of the oranges which he found in that market contained worms, which he described in a general way as resembling those found in chestnuts. We at once wrote him to send us specimens of the infested fruit, if possible, but, although we have not received them, there can be little doubt that this is the larva of the well-known orange-worm, *Trypeta ludens*, which is known to infest oranges in certain districts of Mexico. Professor Cockerell, of the New Mexico Agricultural Experiment Station, in a paper just received, asserts that the oranges from Morelos, Mexico, a district where this insect prevails, have been shipped in considerable quantities into this country during the present season. The shortage of the Florida crop has kept oranges at a price that makes it profitable to export them from that district, and this will explain their occurrence in this country. Few oranges from this part of Mexico come to this port, for they are fit to market at about the time when the Jamaica crop is in season, and with this they cannot profitably compete, but it paid this year to ship them to western cities, and undoubtedly this accounts for their appearance in Denver. As the matter stands, no one need be surprised to find that this insect has secured a foothold during the present year in the orange groves of Florida and California. Orange growers already have enough to contend with, and there is no demand for fresh troubles imported from Mexico or elsewhere, and no one knows how serious a loss might follow the introduction of a new and active enemy.

Professor Cockerell has already written for this journal many articles concerning the scale insects which are imported with fruit, fruit-trees and ornamental plants. In the essay mentioned above he alludes to the well-known fact that our most harmful insects are immigrants, and that we do not know how a species will behave when it reaches a strange land and finds itself under conditions different from those at home. Without its natural checks it may increase inordinately, as did the cottony scale in California. Insects and fungi which infest one plant in one country may find new food in another. We can place no trust in

climatic barriers, for not only can many insects endure great differences of temperature, but they may soon adjust themselves to a new environment, and when Professor Cockerell affirms that scale insects alone, which threaten disaster to our orchards and vineyards, come from all quarters of the globe, the statement is the result of calm scientific judgment based on absolute knowledge, and not the outcome of any childish panic.

Now, there is nothing new in the situation at present, and this threatened invasion of the orange-worm we only use as a text to invite attention to the general fact that while insects and fungi are destroying the crops in this country to the value of a million and a half of dollars every day, there are, perhaps, scores of other larvæ and disease-breeding fungi which would prove quite as destructive as any that are now ravaging our crops if they once obtained a foothold here. And what are we to do about it? Of course, the first thought is a quarantine to prohibit importation into this country of any diseased or insect-infested fruit, tree, plant, cutting or seed; and since it is a national matter the obvious suggestion is that this should be a United States law. Indeed, we have received with Professor Cockerell's essay the draft of a bill which it is proposed to present to Congress at the next session. In a general way this provides that all trees, fruits and other horticultural products should only be allowed to enter the United States at certain ports and under regulations prescribed by the General Government; that all these articles shall be examined by inspectors for such ports, and if clean they shall be entitled to a certificate from such inspector and delivered to the consignee; but if infested with any insect or the germs of any disease they must be shipped back from whence they came or be destroyed within three days from the time of inspection. Now, there is little doubt that Mr. Craw, the efficient inspector of the California quarantine, has done much to protect our horticultural interests from dangerous insects which have entered California ports from Japan, the Sandwich Islands, China, New Zealand, Australia and Mexico, but, of course, the country is not adequately protected with an inspector at one port on the Pacific Ocean. But the difficulty of devising a law for the whole country which shall at once be constitutional and effective is serious, as we have more than once pointed out. Individual states may take action to head off these invasions, but the obstacles in the way of controlling traffic between states seem almost insurmountable. It would seem that Congress ought to be able to shut out the infested oranges of Mexico by a prohibitive tariff, or in some more direct way, just as Germany excludes American pork. But, in order to organize a campaign against this or any specific pest, we must know the dangerous insects and know where they are. It would seem, as Professor Cockerell suggests, that in every country from which we receive plants a competent entomologist should be stationed to determine the presence of pests and warn the people of their probable advent. Professor Townsend's recent travels in Mexico for this very purpose show how much there is to be done, and these traveling entomologists might, whenever the conditions warrant it, inspect the quarantine stations at home and help to keep them in a proper state of efficiency.

The appearance of this Morelos orange-worm illustrates precisely what such an agent might do, for it is only by actually visiting Mexico that it could be ascertained where the infested oranges grow, and once having that information we could have protected ourselves if we had possessed the necessary machinery on the border. Mr. Craw's late reports show that about half the plants which arrive in San Francisco are infested with scales or other insects, and Professor Cockerell is constantly finding new ones. He does not think it necessary that quarantine officers should be skilled entomologists, but holds that any man with sharp eyes, a ready memory, clear printed directions and a set of specimens of the commoner insects could be trusted to guard our interests. We do not coincide with this view.

We consider it absolutely essential that a quarantine officer, if such a position is created, ought to have a considerable knowledge of entomology, with special training and experience.

This whole subject, we are glad to learn, will be discussed at the coming National Fruit Growers' Convention. We cannot afford to sit idly by and allow these repeated attacks upon agricultural industries in their present depressed condition. Fruit growers, truck raisers and the growers of staple farm crops have all they can do to secure a living from the soil. The people who glibly give advice to them "to go into something else," that is, to turn their truck farms into small fruit farms, to abandon the raising of small fruits for dairy products, or to plant vineyards instead of orchards, do not realize how depressing it is to be compelled to revolutionize an entire system of farm economy when the old way is threatened by a glut in the market or by the appearance of some new enemy. It is to be hoped that some means can be devised for the suppression by public authority of pests when they pass beyond the control of individuals. But we must repeat that no more delicate problem than this has ever been presented either to state or national legislation. Some phases of this problem were stated on page 401, in volume vi. of this journal, and we have often discussed the particular cases of the general question. Even if all the fruit, and seeds, and bulbs and plants imported into this country were subjected to rigid inspection it must be remembered that the germs of disease, the seeds of evil weeds and the eggs of noxious insects can be imported in a thousand other ways. When once here the difficulties of preventing their transportation into adjacent states arise, and a spirit of hostility, and perhaps of retaliation, is at once kindled by any attempt to prevent the transportation of infected nursery stock from one part of this country to another. One thing the General Government can do, and the state governments ought to aid it in every way possible, and that is to give moral and financial support to institutions where the scientific study of the contagious diseases of plants and of pestiferous insects is prosecuted, and to give substantial help to the stations where experiments are made to discover the most effective means of eradicating them. The more that is learned about these enemies, and the more widely such knowledge is disseminated, the more certainly we may look for a strong and enlightened public sentiment on this subject, and, after all, this is the one condition essential to the enforcement of a quarantine law or any other direct legislation for the extirpation of infectious diseases or insects.

### Second-growth White Pine in Pennsylvania.

**D**URING a recent trip through Elk, Forest, Jefferson and Clearfield Counties, Pennsylvania, I was repeatedly told that the White Pine never followed itself in forest renewal; that on White Pine lands from which the timber was removed a vigorous growth of hardwoods would appear, but that Pine never came again on such lands, or at least not until the hardwoods had prepared the soil for a second crop of Pine. Among others a leading lumberman of Elk County held strenuously to this doctrine, and this gave an added interest to the examination of the woods. My first stopping-place, after the interview with the Elk County man, so completely refuted his contention that it is hoped he may visit the slashings of the Du Bois tract, and then apply the result of his observations to the care of his own extensive holdings.

In 1859 a cyclone destroyed the timber on a strip of land half a mile wide and of great extent, its path crossing the Du Bois tract in the north-west part of Clearfield County. A new growth has, of course, sprung up in the path of the storm. Upon one part of it, which by a fortuitous combination of circumstances has been protected from fire, there is a vigorous stand of young White Pine, mixed with hardwoods. Seen from an adjoining hill the Pine seems the

most plentiful species, and a careful study resulted in a surprisingly small percentage, but explained measurably the erroneous theory regarding the absence of White Pine generally in second-growth timber.

An acre, believed to be representative of the protected area, was measured off and all the trees counted, resulting as follows: White Pine, 285; Aspen, 66; Beech, 138; Sugar Maple, 130; Silver Maple and Red Maple, 130; Black Oaks, 16; White Oak, 1; White Ash, 24; Cucumber Tree, 96; Black Cherry, 79; Black Birch, 432; White Birch, 12; Basswood, 6; Ironwood (*Ostrya*), 2; Tulip Tree, 13; Chestnut, 2; Willow, 10; Hemlock, 50.

To this list must be added a shrubby undergrowth of Alder, Blackberry and other plants.

It will be observed that of the 1,480 trees counted on the area, only 285, a little less than one-fifth, are Pines. Of this number 90 were estimated at forty feet or more in height. These Pines were the tallest trees on the acre, and this fact, coupled with their winter foliage, gave them the appearance of being the most numerous. The tallest Hemlock on the acre was hardly more than six feet, while the great majority of the Hemlocks were less than two feet high.

The age of the oldest Pines was found to be thirty-five years, showing that they sprung up within a few years of the destruction of the old growth.

An effort was made to determine the age of small Pines by pulling a number of trees up to three feet in height and counting the annual rings at the collar, using the number of whorls of branches as a check. For this purpose a "slashing" (land whence the merchantable timber has been cut) not far from the sample area above noted was carefully examined. Immediately adjoining the slashing was a splendid Pine forest, where there stood an average of thirty-five Pines to the acre, the remaining trees being Hemlock and a small admixture of hardwoods. In the slashing the ground was covered with a dense growth of Brambles, young Maples, Birch, Beech, etc., rising to a height of ten or twelve feet. It was evident that fire had not touched the tract since the timber was cut, and a careful examination revealed a number of young Pines growing healthily in the shade of the hardwoods. Unfortunately, a fall of snow prevented the counting of the little Pines on measured areas. Between forty and fifty trees were pulled, their ages determined and height accurately measured, the result being as follows: Two years old trees, 3 inches high; three years old, 5 inches; four years old, 8 inches; five years old, 10½ inches; six years old, 31 inches; seven years old, 31 inches; eight years old, 27 inches. It is not to be inferred, of course, that the growth of Pine becomes less the seventh and eighth years; it simply happened in this instance that the twelve trees of which the size was determined had not made as good growth as those of less age. It will be noted that during their first four or five years the White Pine seedlings grow very slowly, and it is easy to understand that there might arise a doubt of their ever making large trees, compared with the more rapid-growing hardwoods which shelter them. So, too, the tiny seedlings might easily escape notice entirely, and thus the false generalization with which this article is headed is explained. However, in studying the development of the young growth on the sample area above noted, it was found that the Pine begins a rapid height growth when from ten to fifteen years of age, and between the ages of fifteen and fifty years it is no unusual thing for it to increase in height from two to three feet in a single year. Thus we find in the slashing tiny Pines which require a sharp lookout to discover, while in the path of the cyclone, other conditions than time being similar, the lusty Pines seem to dominate all the other growth.

The two instances above cited demonstrate the ability of White Pine to reproduce itself, provided fire is kept away from it. The proviso sounds simple enough, but the thousands of desolate acres marked by charred stumps and ash-covered soil which lie between Williamsport and

Warren along the line of the Philadelphia & Erie Railroad, prove that there must be some extraordinary difficulty in protecting from fire lands that have been cut over.

Washington, D. C.

Charles A. Keffer.

## The Arrangement of Flowers.—II.

### LONG-STEMMED FLOWERS.

AN equally important class of flowers for table decoration are the long-stemmed flowers. Two flowers prominent in most gardens, poppies and roses, may be taken as examples. I like the clear, slender glass vases for flowers, especially the ones that show the leaves and stems down to the base. Highly ornamental vases of any description are not appropriate, and the flowers themselves must be the conspicuous feature. There are, of course, exceptions. At a luncheon the central decoration of the table was a succession of little Dresden lords and ladies holding pictures and cornucopias as large as themselves, in which were a few rare roses and Orchids. The effect was pleasing, but these choice flowers, unlike our ordinary garden flowers, seem to harmonize with costly porcelain. Hare-bells and Trailing Arbutus would have looked altogether out of place in the same vases. Winter hot-house flowers show to good advantage in Bohemian cut glass and other handsome vases. In summer, in the country, for flowers of the fields and woods the vases should accord with the house and surroundings; but no positive rule can be laid down for appropriateness or good taste in their choice, and good sense is the safest guide. It is difficult to arrange flowers to have an artistic effect in a rose-bowl. The principle of the rose-bowl is wrong, and a vase should be smaller at the bottom than at the top. The tall, slender green or white vases which look like huge morning-glory blossoms are beautiful for flowers as well as appropriate. The flowers grow in this way, the bushes small at the base and broader toward the top. A Poppy garden should contain fancy grasses, and no arrangement of poppies is perfect without some of these, while oats, wheat and timothy contribute to a harmonious effect. Only a few poppies should be placed in a vase, so that the effect may be light and delicate. They are a fairy-like flower, and the spirit of the flower should be carried into the arrangement. As many as sixteen tall, slender lemonade glasses may be disposed on the table for only about fifty poppies. The finished effect is that of poppies growing, and each delicate petal shows to its best advantage. Any number of glasses may be placed in some definite order down the centre of the table, such as first a central one, then four surrounding it, then a chain of three at the two ends of the square. The grasses should be put in highest at the centre, leaning first one way and then another, just as they grow. The highest poppies also should be placed in the centre, and perhaps the darkest ones, and the lighter and smaller ones used until the small glasses at the ends of the chain hold the finest and most delicate of all. Fewer flowers are required for an arrangement of this sort than one would think, and showy displays may be made with no more blossoms than are sometimes seen crowded into one vase, when the only effect is a mass of color.

Roses may be treated in much the same way, substituting Maiden-hair or other Ferns for the grasses, or using only their own beautiful waxy leaves.

Rangeley, Me.

Dorothy Root.

## The Islands of Lake Champlain.

IT has long been an accepted notion that the shores and islands of our great lakes offer special advantages in fruit-growing. Some of the most noted localities in America for the production of apples, peaches and grapes lie along or in the Five Great Lakes. Lake Champlain ranks in size below only these, yet contains an island area greater than any. The fruit-growing industries on the Champlain islands, however, have but recently begun the course of development for which the location gives so

much promise. But apple-growing is now gaining rapid headway, and it seems probable that fruit-raising will soon be the distinctive industry of the islands.

Several of the smaller islands along the western shore belong to the state of New York, but the greater islands are all parts of Vermont. These are principally included in Grand Isle County, which is the north-western county of the state. The whole of this county is surrounded by the waters of Lake Champlain, except a narrow neck which connects the town of Alburgh with Canada. Grand Isle County consists of three large islands and the peninsula mentioned, together with several unimportant smaller islands. This constitutes an insular area of eighty-two square miles, of which 47,250 acres are in farms (Census of 1890). Alburgh, the peninsula town, is considerably the largest one in the county. The island of South Hero has an area of about 20,000 acres, is about twelve miles long, and varies from one-fourth to five miles in width. North Hero is a long, narrow island of irregular form, containing 6,272 acres. Isle La Motte is two miles wide and six miles long, containing 4,640 acres. These islands are separated from each other by very narrow straits at certain points, and from the mainland by a width of water varying from half a mile to several miles.

There can be no question but that the surrounding waters of Lake Champlain materially modify the climate to the favorable prejudice of fruit-growing. There seems to be no satisfactory way, however, of measuring the extent of this modification except by its effects on plant-life. Such purposes of comparison may be served by stating that such apples as Northern Spy, Rhode Island Greening and Ben Davis thrive, while Baldwins are not long-lived, and King of Tompkins County is decidedly uncertain. Last winter all fruit-buds of Japanese and Domestica varieties were frozen, but this is unusual. Peaches have been grown under special protection.

Vermont Experiment Station.

## Entomological.

### The Strawberry-root Louse, *Aphis forbesi*.

THE Strawberry-root louse is found throughout the state of Delaware and probably throughout the peninsula, although it has attracted attention only in a few localities, and too often the grower of Strawberries is not sufficiently intimate with the pest to detect its presence until his plantation is practically ruined. To one who knows it, however, its presence or absence is generally revealed as soon as a plantation is entered. Bare spaces scattered throughout the field at once arouse suspicion, but when it has intrenched itself in sufficient numbers to attract attention to its actual devastation, the Strawberry-bed will disappear with remarkable rapidity. In a plot at the station, containing about seventy-five varieties, which were in a flourishing condition in the spring of 1896, there are not a dozen varieties remaining.

This louse is a small dark bluish green insect, oval in shape, which gathers in great numbers on the roots and often in the crown of the plant, and there pumps out the juice. The eggs can also be seen in both of these situations, and are minute, oblong, shiny black bodies. The aphid is attended by a small brown ant (*Lasius alienus*), which probably bears the same relation to this species as it does to the Corn-root louse. I am not aware that any winged form has been discovered, and its passage from field to field must be slow, or practically impossible. The most practical form of treatment at present is in the rotation of crops, whereby the aphid may be starved out. The most probable means of distribution is by infected plants coming from the nursery, where its presence has not even been suspected. It is easily treated on nursery stock with bisulphide of carbon, kerosene emulsion or tobacco-water.

The life history of the aphid has not been carefully worked out. It was first discovered and figured by Pro-

fessor S. A. Forbes, of Illinois, in his Thirteenth Report, page 102, but the specific name, *forbesi*, was not given to it until 1889, when Professor Weed, of the Ohio Station, vol. ii, No. 6, named it in honor of Professor Forbes.

## Foreign Correspondence.

### London Letter.

**SAXIFRAGA STRACHEYI.**—This plant was introduced from the Himalayas fifty years ago, since when it has always been grown here and there in a sheltered place on the rockery, where it produces its large corymbose clusters of red flowers in April or May. It also proves to be an excellent plant for pot-culture to flower under glass in February. The thick fleshy rhizomes are established in pots during the summer, which is easily done, and they are kept in an unheated frame till January, when they are placed in a temperature of about fifty degrees in a light position. This induces them to push up their flowers, and by the middle of February plants in six-inch pots have from three to six clusters, as large as an ordinary bunch of grapes, of rosy pink flowers. The only defect they have is due to the absence of leaves, which do not develop till after the flowers have faded, but this defect is easily remedied by a little arrangement. *Saxifraga ligulata* may be grown in the same way, and it develops its leaves at the same time as the flowers; the latter are pure white when forced.

**SPRING-FLOWERING IRISES.**—Given a mild winter, we have Irises in bloom in the open air all through the winter. Herr Max Leichtlin notes the flowering of the charming little *I. Histrio* with him in November last. I have seen it in bloom several times since Christmas, and at the last meeting of the Royal Horticultural Society (February 9th) it was shown in beautiful condition by Messrs. Wallace, of Colchester. We have beds of *I. reticulata* in full flower on our lawns now, and in other parts of the garden the allied *I. Bakeriana*, *I. histrioides*, *I. Krelagei*, *I. sophenensis*, *I. Vartani* and *I. Kolpakowskiana* have been lately or are now flowering nicely. These Irises belong to the same category as Snowdrops, Snowflakes, Winter Aconites, blue Squills, *Chionodoxas* and early Crocuses in their value for early spring effects. They are easily managed, they flower freely, and they are of the most charming shades of blue. We cannot have too many of such plants in gardens where they will do in the open, and where they will not they are worthy of frame culture. It is singular that our earliest spring flowers are blue or white, followed by yellow.

**CROCUS SUSIANUS**, better known in gardens as *C. reticulatus* or the Cloth of Gold Crocus, is a variable species and one of the forms is decidedly distinct and beautiful among the many species of spring-flowering Crocuses in bloom with us now. The leaves are short, the flowers are of medium size and short-stalked, and the upper or inflated part of the tube is of a rich orange-yellow color, the outer segments being covered with almost confluent streaks of brown-purple. In dull weather the segments do not close upward, as in other kinds, but they curl down and inward, or revolutely, so that they are always attractive. Probably this character was recognized by Haworth when he named this species *C. revoluta*. It is a native of the hills of the Crimea and of Asia Minor. This must not be confounded with the common yellow or Dutch Crocus of gardens, the flowers of which also are striped with brown outside, but which are larger, coarser, of a different shade of yellow, and they do not possess that revolute character of segment so characteristic of *C. Susianus*.

**THE BEST SNOWDROPS.**—First I would place *Galanthus nivalis*, which grows wild or naturalized in many parts of this country and Ireland. It lives and multiplies among the grass under deciduous trees, and is charming in modest patches in the garden or when covering acres in the park or plantation. The largest-flowered and most striking species, however, is *G. Elwesii*, with which we have been familiar for twenty

years, and which is now grown in large quantities in all good gardens. Here it will not live more than a year or two in grass, but in a north border we have a large colony which is as thick now as when planted three years ago. Considerable variety is shown in the size and form of the flowers and also in the width of the leaves of this species, where it is grown by the thousand. The largest flowers I have seen this year are one and a half inches long, and the widest leaf an inch. Several have developed two flowers on a scape. The third is *G. Ikarie*, introduced from Smyrna in 1893, and now abundant in English collections. It has broad, bright, shining green leaves and long, pointed "drops," the inner segments being marked as in *G. nivalis*.

**ADONIS AMURENSIS.**—I noticed this Japanese species last year when it flowered for the first time at Kew in February. It is flowering again now and is better than it was last year, the flowers being larger and of a brighter yellow. So far it has proved quite hardy. The stems, which spring in a dense cluster from the root-stock, are from nine inches to a foot high, clothed with elegant dark green feathery leaves and terminated by short-stalked Anemone-shaped flowers, two inches in diameter. It is a native of Japan, where it is a popular garden plant and is represented by a considerable number of varieties.

**TULIPA VIOLACEA** is the first Tulip to open its flowers this year. It is a dwarf species, related to *T. sylvestris*, about six inches high, the flowers two inches long and colored red-purple, with a blue-black blotch at the base of the segments. It is a native of Persia, from whence it was introduced through Herr Max Leichtlin a few years ago.

**LILIUM GIGANTEUM.**—This stately Lily grows well along with the hardy Bamboos at Kew. A plant which flowered in 1895, and afterward yielded a quantity of seeds, offered a good opportunity for securing a big batch of seedlings; accordingly, the seeds were sown in shallow boxes in October, and these were placed in a greenhouse where Cape bulbs are grown. But the seeds did not germinate in the spring as expected, and it was conjectured that a higher temperature would wake them up. One of the boxes was removed into a tropical temperature, but even here the seeds showed no signs of vegetating. And now, after waiting sixteen months, the seeds are germinating freely, those in the cool being just as forward as those in heat. The lesson to be deduced from this is that seeds of *L. giganteum* sown as soon as ripe take over a year to germinate, whether sown in a tropical or cool temperature. It takes from five to seven years to grow a seedling to flowering size.

**LILIUM AURATUM.**—The Japanese growers, or those who are responsible for the preparation of the bulbs for export to Europe, have not been successful this season with this popular Lily. Thousands upon thousands of the bulbs have arrived here quite rotten, so that, although the consignments have been greater than in any previous season, the number of sound bulbs actually received has been a long way below the average. Is it possible that less care is taken in the cultivation and harvesting of the bulbs than used to be the case, or is the fault in the packing? At any rate, the failure is much deplored by would-be buyers here. Has this Lily ever been tried in Bermuda? It would, if successful, prove a better venture than *L. Harrisii* even. I offer the suggestion for what it is worth. England alone can take hundreds of thousands of bulbs of *L. auratum* if the price is reasonable. *L. Henryi* is another Lily worth farming on a large scale.

**NATIONAL VIOLA SOCIETY.**—The modest Pansy has risen to the dignity of a Society all to itself. Mr. W. Robinson, who is the President, is, no doubt, also the prime mover in this very laudable effort to develop the Pansy family, or rather to bring it into that prominence which, from its variety, merit and adaptability, it eminently deserves. The first annual meeting of the Society was held last week when it was decided to repeat the exhibition held in the gardens of the Royal Botanic Society, Regents Park, last year, when the display of Pansies, Violas, etc., was the largest of the

kind ever held in the south. I have before described the beautiful effect produced in Mr. Robinson's garden at Gravetye by planting bedding Violas of differing kinds to cover the soil of his Tea Rose beds, and I have seen equally beautiful effects obtained by using these plants for ordinary bedding. In hot dry weather they are apt to suffer unless the soil is retentive and kept moist by watering. We have now a considerable number of breeders at work among these plants.

Fig. 12.—*Agave attenuata*.

## New or Little-known Plants.

### *Agave attenuata*.

A MAGNIFICENT specimen of this stately *Agave* has been in bloom for several weeks in the United States Botanic Garden at Washington, and is reproduced in the illustration on this page. This is the first time the species has flowered in Washington, and, from a rather hasty examination, it appears to be the first time it has flowered in this country. The plant now in flower was bought in Such's nursery by Mr. W. R. Smith more than twenty years ago. Its previous history is unknown, but it

undoubtedly came from Mexico, the home of the species. The flowering plant differs from figures and descriptions in having a perfectly erect, stiff spike of flowers, instead of being curved. In all the other characters the plant differs very little from the description of *A. attenuata*. In our specimen the woody stem below the crown of leaves is four feet high and one foot in circumference at the thickest point, which is a short distance below the crown. It is marked with quadrangular scars, three to four inches wide by one inch deep. The crown, which consists of twenty or more immense leaves, is, indeed, a handsome sight, measuring as it does nearly six feet in diameter. The leaves are first erect, but when mature they are spreading, and in age drooping, the lower ones gradually falling off, leaving the peculiar scars referred to above. The larger leaves are from two and a half to three feet long, from six to eight inches broad at the widest point, which is about two-thirds of the distance from the base, gradually tapering to near the base, where they are three or four inches wide, while they rapidly taper upward into long weak spines; the leaves are very glaucous on both sides, while the margin is entire and thin, at first whitish, but in age brownish. During the flowering period the larger leaves drop off, leaving only ten to twelve, which are not more than two inches in width and two feet long. The peduncle is only about one foot long, but is very thickly covered with large leaf-like bracts, somewhat appressed, but spreading at the base, and acuminate. The flowering spike is very dense and fully five feet long; the flowers are in twos subtended by bracts; these bracts are green, attenuate, horizontal, the lower ones being five inches long. The flowers are mostly sterile, the perianth tube very short, the stamens much longer than the petals. This plant has been in bloom nearly three months, while it was nearly two months in developing its flower-spike.

The species was first described by Salm Dyck in 1834. It was afterward (1862) described by Sir William Hooker as *Agave glaucescens* in *The Botanical Magazine*, and is sometimes found in cultivation as *A. spectabilis*. It has been illustrated in *The Revue Horticole*, figs. 31 and 32 (1875); in *The Botanical Magazine*, t. 5333 (1862), and in *The Gardeners' Chronicle*, fig. 55 (1887), figs. 63 and 64 (1895). It was introduced into cultivation about 1834. It flowered first at Kew in 1861, and has flowered several times since. It is reported in *The Gardeners' Chronicle* to have flowered in the Coimbra Botanic Garden in 1886 and 1887, in the garden of Mr. Hanbury at La Mortola in 1890, in the gardens of His Majesty the King of the Belgians at Lacken in 1895.

The plant has been widely distributed in gardens, and will doubtless be frequently found in flower in the future.\*

Washington, D. C.

J. N. Rose.

### *Iris Hartwegii*, Baker.

FREQUENT inquiries about this pretty *Iris* show that it is a favorite, and lead me to put on record what I know about the species.

*Iris Hartwegii* occurs in California at elevations of from 1,300 to 4,500 feet, in a belt almost exactly coinciding with that occupied by *Pinus Lambertiana*. Like this Pine, it does far better on cool, protected northerly slopes than on shallow-soiled hot slopes facing south. The fact that its large clumps die out if the surrounding Pines and shrubs are cleared off, proves that this *Iris* prefers the shelter, and it does well even when the needles from the Pines smother almost everything else on the ground. The tufts may be small or as much as twenty-four inches in diameter. I have seen whole slopes covered with them. The tender India-yellow color fades in the hot sun very rapidly, but a field of these flags, lit up by the rays of the sun fall-

\* The most important references to the species are the following:  
*Agave attenuata*, Salm Dyck, *Hort. Dyck.* (1834).—*Rev. Hort.*, 149, figs. 31 and 32 (1875).—*Gard. Chron.*, ser. 2, viii., 748 (1887).  
*Agave glaucescens*, Hooker, *Bot. Mag.*, t. 5333 (1862).—*Gard. Chron.*, ser. 2, viii., 748 (1887); ser. 3, viii., 560 (1890); ser. 3, xvii., 457, h. (1895).

ing through the stand of Pines, is a beautiful sight. The stems range from twelve to eighteen inches at the lowest limit of the plants, to but six or eight inches at its highest range. The size of the flowers varies but slightly, though the falls and standards are somewhat reduced in the highest altitudes.

The climatic conditions under which it grows are naturally varied when so wide a range suits this species. The lowest temperature at the height where it begins to appear was 22 degrees, Fahrenheit, in eight years of observation, the highest 112 degrees. Although the seeds from which most trees of the Sugar Pine (*Pinus Lambertiana*) are raised have been gathered at altitudes between 3,000 and 4,000 feet, it must not be expected that Iris gathered from low limits would do equally well in eastern gardens. The dwarfed plants at 4,500 feet altitude are exposed to very severe winters, tempered only by the heavy snows which fall in those regions. At Panther Creek, Amador County, I have known snowfalls ten feet in depth, while one winter in about five may not know snow deeper than ten inches. Good drainage seems essential to the growth of this Iris, and, above all, a period of rest during the whole summer. In our Sierras, at the altitude of 1,300 feet, no rain falls after the middle of May, unless there happens to be a shower about the Fourth of July, until in fall when the advance showers of winter set in about the middle of September. The mean rainfall at 1,300 feet elevation is about thirty-five inches, most of which falls during December, January and February.

Applying these observations to eastern conditions, I would say *Iris Hartwegii* should have the most sunny place in the garden, unless your summer equals the extreme heat I have recorded. It should be well up on a slope, above a rock wall, or in a similar position, and kept from freezing too deep in the ground. While there are far more gorgeous Irises to be found, and most of them are more easy of cultivation, it is the charm of succeeding with what seems refractory which will add greatly to the pleasure of cultivating *Iris Hartwegii*.

Berkeley, Calif.

George Hansen.

## Cultural Department.

### Notes on Hardy Plants.

MANY hardy plants in cultivation are valued mainly because they come into bloom very early in spring, when there is a dearth of bloom outside of the greenhouse, or because they bloom late, when most other flowers are past. *Helianthus Maximiliani* belongs to a very late-blooming class; it hardly matures its flowers here in Vermont, and it never seeds here. It seems quite hardy, and, if not so late, would be a good plant for this section. Its lateness should be in its favor a little farther south. It never has had a chance to develop its full height here, but I understand that it grows to be eight feet or more high in the latitude of New York.

One of the best Sunflowers I have tried here is the Willow-leaved *Helianthus*, *H. orgyalis*. It is a tall and stately plant, which, under favorable conditions, attains a height of eight and ten feet. It is also late in blooming, but its flowers come to maturity here. These are orange-yellow, not large, but numerous, borne in large panicles, and they last a long time. It takes more than a severe frost to injure them, and nothing short of a freeze which kills most plants seems to affect it. The long stems are well set with narrow drooping leaves, which give it an attractive appearance during the entire growing season and until winter has fully set in. This continuous attraction throughout the season is seldom found in hardy perennials. The plant shows to best advantage when massed in a round bed. It spreads from the root quite rapidly, and a few plants soon form a large clump.

*Erigeron glaucus*, of western North America, has much to commend it to growers of hardy perennials. In good garden soil it attains a height of ten to fifteen inches, and bears good-sized flower-heads of a purplish hue. It needs only ordinary garden soil to succeed.

The Willow-leaved Ox-eye, *Bupthalmum salicifolium*, of Australia, grows a foot and a half high, with good-sized flower-heads of Daisy-like shape, resembling those of *Coreopsis lanceolata*, but of a deeper orange shade. It is perfectly

hardy here and grows freely without extra care. It blooms in early summer and continues for a considerable time.

For rock-work in full sunlight, or in sunlight half the day, the Barrenworts (*Epimediums*) make a pretty group. *E. violaceum*, which is a variety of *E. macranthum*, is the most robust grower with me. All the species do fairly well here after they are established. The foliage is their principal attraction, though the flowers are pretty. *E. niveum* has delicate white flowers, and those of *E. sulphureum* are of a sulphur-yellow shade. *Epimediums* are propagated by division of the root, and this is best done in the latter part of the summer.

Charlotte, Vt.

F. H. Horsford.

### The Japanese Ampelopsis.

A FEW hints on the cultivation of this deservedly popular climber, *Ampelopsis tricuspidata*, or Veitchii, as it is sometimes called, are likely to be useful, especially regarding the raising of young plants; this may be done from cuttings or seeds. The latter method probably entails the least labor and trouble, but when uniformity is desired the plants must be grown from cuttings, for the seedlings are apt to vary greatly in size, in form of leaf and in vigor of growth. All the plants assume more or less gorgeous tints in fall, but the coloring varies so much that harmony can only be had from carefully selected cuttings. The cuttings should be young growing points taken with a heel toward the end of the summer, and struck in sand either in a cool propagating-bed or a cold frame, or inserted singly in small pots in a free sandy compost. They quickly strike root and become well established before the leaves fall off. They should be kept dormant through the winter and protected against severe freezing. In spring they may be planted while yet dormant, or after they have started a little.

Seeds germinate best when sown soon after they are gathered, which is usually about the beginning of November. I have seen the berries sown entire, but it is better to wash the seeds out. They should be sown in flats in a light sandy compost and lightly covered. Germination is somewhat slow, but nearly all will come sooner or later if the seeds were thoroughly ripe when gathered. The soil must not be kept too wet, or the seeds will rot after germination has taken place. The seedlings will be ready for potting into small pots about the middle of February, and it is not advisable to attempt this operation earlier, as nothing is gained by handling the plants when very small. One more shift will be required into three-inch pots; they can then be planted about the end of May, having previously been gradually hardened off. These plants are not particular as regards soil in their permanent quarters, but if it is poor where the plants are to be set it is worth the labor to remove it and replace it with soil of a better quality. The plants should be set close to a wall, and a fastening of some sort provided to keep the shoots attached until they have made sufficient growth to enable them to cling of themselves. Carefully handled young seedling plants under favorable circumstances will grow to be eight to ten feet high the first season, with an abundance of luxuriant foliage. Planted about three feet apart they will do much to beautify an unsightly wall in one season.

If the wood is not sufficiently ripened the fall after planting slight protection may be needed, otherwise this is not necessary. Branches of evergreen trees placed against the wall over the plants make a convenient covering.

Tarrytown, N. Y.

William Scott.

### Carnation Notes.

BY this time most growers will have inserted cuttings for next winter's plants; some easily rooted and quick-growing varieties, such as Daybreak, Alaska and William Scott, will still make good stock by planting-out time, but I prefer to have the main portion in somewhat earlier, as a much larger percentage of the plants will root in January and February than later in the season, when it is more difficult to avoid extremes of temperature. Our cuttings will be boxed off about the middle of March; this will allow ample time for them to make nice plants by the time they can be transferred safely to summer quarters early in May. Plants rooted during December and early in January expressly for summer flowering are now in boxes on the shelf of a cool house. The cuttings have been stopped once, and will shortly be transferred separately to three-inch pots. About the end of March they will be placed in a frame in which a few inches of warm manure has been well-tramped down and covered with a coating of coal-ashes. If potted much earlier the little plants are liable to become

pot-bound, and do not start so well when set in the open ground. A good list for outdoor flowering is the following: Mrs. Fisher, white, still the best of the whole section; Ferdinand Mangold and Sebec, crimson, the latter a seedling raised by Mr. Nicholson, of Framingham; William Scott, Nicholson and Abundance, pink; Daybreak, shrimp-pink, and two scarlet seedlings. We have not found any striped or yellow varieties which will bloom profitably, but purpose trying a few of the newer sorts this summer again.

Plants in the benches are now requiring more liberal waterings and more frequent applications of fertilizers. We prefer to allow the soil to become moderately dry before watering, and then give it a thorough soaking. Our plants were recently picked over and all decaying foliage and useless growth removed, after which a mulch of well-pulverized, but rich, manure was given, and a further and heavier mulching will be given before hot weather sets in. Every year we find something new in Carnation-culture, and one important point is that these plants will thrive on more frequent and richer applications of liquid foods than they usually receive. We must bear in mind that they have but a few inches of compost to grow in to begin with, and having already been in the benches nearly six months they have extracted most of the available nourishment from the soil. To keep them growing and flowering vigorously it is absolutely necessary to feed them well. At present I am giving liquid fertilizers once a week, using sheep manure, sulphate of ammonia and cow manure, alternately, of moderate strength. We use some soot with the manure. As the season progresses the strength of the nutriment will be increased.

Rust, which attacked one or two varieties quite badly earlier in the winter, has now almost disappeared. Diseased plants are sprayed regularly with the arsenical solution, and badly affected or decaying foliage is picked off. At this season ventilation can be freely given on most days. Carnations detest coddling, and if they enjoy a free circulation of air stouter stems and fewer burst calyces will be seen. It pays to disbud all varieties, and this practice is almost universally adopted now. Some sorts, like Jubilee, Eldorado and Daybreak, need little disbudding, but, on the other hand, McGowan, William Scott, Portia and Hector make a large quantity of side-buds, the last-named being, perhaps, the worst to handle. The flowers of some sorts, particularly those of pink shades, fade quickly when exposed to strong sunlight. Blooms of William Scott should be picked before they fully expand, or they will not hold their color, and Daybreak blooms lose their lovely shrimp-pink shade if left on the plant a day too long. All Carnations should be gathered and placed in water in a cool room some hours before being used. Florists now adopt this plan, and the blooms swell out half as large again, the stems become more rigid, and the flowers after long shipment are found in a much fresher condition than if they had been picked, packed and dispatched at once.

Complaints are heard this season from various flower markets that the popular William Scott has to some extent lost its favor with the public, and the prices realized on this variety are lower than on almost any other sort marketed. It has proved such a money-maker for the past two or three years that every florist has been tempted to grow it largely, and the markets have at times been glutted with it. Before we can afford to dispense with it, however, some superior new variety must be introduced to take its place. It is the most persistent bloomer we grow; its one drawback is that the flower fades if not picked before becoming fully expanded. It yields three times as many flowers as any other pink variety we have grown, and we do not expect to see it discarded or relegated to an inferior place for a year or two. Madame Diaz Albertini is only grown to a limited extent, and it does not bloom freely enough to be profitable. Neither does Bridesmaid, although it produces an excellent flower on a first-class stem and holds its color well. Where quality rather than quantity is desired it is worth retaining. Triumph, certificated at the Carnation Show in Boston in 1895, proves rather disappointing and does not bloom freely. Abundance has short, stiff, wiry stems; the flowers are of fair size and good color, and it is a more persistent bloomer than any other new sort I have tested. Della Fox was very rusty earlier in the season, but is now almost clean. It is not popular in this section as its color is not fancied so much as the paler and more reliable Daybreak. Its general habit is better than that of Daybreak, but it is not likely to attain anything like the popularity of that kind. In dark shades Thomas Cartledge proves reliable, but we still retain a few plants of the good old variety Tidal Wave, which, as a general rule, is rather a dwarf grower, although our plants this year yield stout stems eighteen inches long, in clayey soil. Some promising new

pinks, such as Victor, Mrs. McBurney, C. A. Dana and one or two others, are offered for the first time this season. Some good scarlets appear to have been exhibited in the seedling classes at the Cincinnati Show, and a reliable scarlet sort of good size is much needed. We grow Hector chiefly, a variety raised by Mr. I. Wright, of Wellesley Hills. In color and size of flower it is all that could be desired, but it produces far too much grass and lacks strength of stem. Its flower mounted on a stem like that of Jubilee would be superb. Jubilee has proved the premier scarlet at the great Carnation Show. The flowers shown at Boston in 1895 by the raiser, Mr. E. G. Hill, had the finest stems of any variety exhibited, and at Cincinnati it has eclipsed all others of its color. We grew a few plants of it this season, which were very small when housed and did not flower until Christmas. They have produced some first-rate blooms on perfect stems and with an exquisite odor. The plants were rusty early in the season, but are now clean, and we hope to secure better results next winter from cuttings rooted earlier. Every shoot produces a flower, and after one crop is picked the plants look like stumps, but soon throw up another set of flowers. There will be no use for such small varieties as Portia and E. G. Hill where Jubilee will succeed.

Eldorado has proved the most reliable yellow variegated sort we have ever grown, and we consider it the best of its class sent out up to date. It is a very free bloomer and we have not been troubled with any burst calyces. It quite eclipses Bouton d'Or, which was one of the star yellows in 1895-6. Buttercup occasionally gives a superb flower, but it is not a persistent bloomer like Eldorado. The blooms hold fresh on the plant longer than any other sort we know; a flower kept in good condition over three weeks in February. The new variety, Mayor Pingree, raised by John Breitmeyer & Sons, Detroit, will make a strong bid for public favor next year, judging from flowers we have seen. Helen Keller this season has done the best of any of the white variegated section with us, from plants grown in heavy clay loam. Armazindy, sent out by E. G. Hill & Co. last year, has a superb stem and gives occasional exceptionally fine flowers, although the plant has rather a sprawly habit. One or two promising new sorts in this class are now being put on the market, but I do not know enough of them to venture any judgment.

Lizzie McGowan has been more widely and largely grown than any other white the past season, and the flower markets have suffered from a glut of it, as in the case of William Scott. Though inferior to some of the newer sorts in size and form, it is still an admirable all-round kind. Alaska is also good and popular, although care must be taken in propagating it to select cuttings from the cleanest and most robust plants, or there will be danger of leaf disease. Crystal, raised by Mr. Fisher, of Framingham, has a huge flower, but it bursts badly here in winter and does not prove a very free bloomer. Edith Foster, sent out by Peter Fisher & Co., Ellis, Massachusetts, is well liked where grown; the flower is not very full, but is produced on a good stem and it is quite prolific. Mrs. Fisher is still clung to by some growers, and for outdoor blooming it is indispensable. Occasionally it is seen well grown, as at Mr. Tailby's, of Wellesley, who finds it the best money-maker on his place still. Flora Hill, the champion white at Cincinnati, and Harrison's White, said to be a sport from William Scott, are two novelties likely to be tried in many places next winter. Nothing in crimsons yet beats F. Mangold with us. Meteor we will discard after two years' trial.

Taunton, Mass.

W. N. Craig.

**Hardy Ferns.**—Every one who has a garden, however small, can find a place for a few hardy Ferns, particularly of our common native sorts. What they require first and above everything else is shade, and this means that they will thrive best on the eastern or northern side of a dwelling or wall, or in any other situation where the afternoon sun does not strike them fully. It is not usually best to plant them under trees, for the roots of trees rob the soil of the moisture which is needed by the Ferns, and besides this, streams of water after rains will flow down from the branches on some of the fronds much to their injury. I have an interesting and thrifty collection of native Ferns which are planted on the eastern side of a house, where they have the sunshine until noon, but after that they are in shade. Among twenty-five species and varieties which can be collected in the vicinity of Philadelphia, half a dozen are evergreen, and all of these should be planted. The best time to collect is in the late summer. They can all be found at that time, and their fronds being fully matured the height which they attain is shown, and when their size is known the proper place for them in the garden can be determined, and the room they require can be set apart for them.

It is an easy thing to get all the roots, so that they are not difficult to transplant, although, of course, it is better to take as much of a ball of earth with them as possible.

Germantown, Pa.

Joseph Meehan.

## Correspondence.

### Diseases of the Snowberry.

To the Editor of GARDEN AND FOREST :

Sir,—Early in June last I observed on the leaves of my Snowberry-bushes, *Symphoricarpus racemosus*, a mildew which was accompanied by a black spot, affecting a portion and sometimes the entire leaf. As the fruit began to develop I noted black spots showing on the berries, and by the first of September it was impossible to find a perfect fruit, and these, with the diseased foliage, gave the shrubs a most unsightly look. About a half a mile from these diseased shrubs I had a hundred plants of the same species which were not badly infected, but they all showed symptoms of the disease in a greater or less degree. Will you be kind enough to tell me whether this is a local trouble, or whether it is one generally known? I hope to get a vigorous growth of these plants by using manure and check the disease by spraying with the Bordeaux mixture. Is this good practice?

Huntingdon Valley, N. Y.

L. F. Horner.

[It is impossible to decide just what malady it is that has affected Mr. Horner's shrubs without examination of specimens. Dr. Halsted, to whom the inquiry was sent, states that there is a mildew, *Microsphaera Symphoricarpi*, which was described by Mr. E. L. Howe, of Yonkers, New York, in the fifth volume of the *Torrey Bulletin*, page 3; and manuals upon Fungi show that this mildew is not unknown in various parts of our country. It also affects other species of this genus, for Dr. Burrill records it upon *Symphoricarpus vulgaris* in Illinois, and Dr. Halsted has seen the same fungus on Snowberries in Pennsylvania. The black spots on the leaves are probably due to another fungus, and there is a leaf-spot, *Phyllosticta*, which infests the Snowberry, but it is a European species and has not been reported in the United States. There is another leaf-spot which is truly American, however, a *Septoria*, and it may be this which is working together with the mildew upon the foliage of Mr. Horner's plants. It is harder to suggest an identification of the disease which spots the fruit. Almost every one has seen specked Snowberries, but Dr. Halsted says that he has never made any study of the nature of this trouble, and it may be caused by any of the fungi mentioned above in connection with the mildew and the leaf-spot. Very probably these enemies can be controlled by spraying with the Bordeaux mixture if it is tried early and continued during the growing season; and since the disease is probably a widely spread one, this hint may be useful to others besides Mr. Horner.—Ed.]

### The "Ramie" Fibre Plant.

To the Editor of GARDEN AND FOREST :

Sir,—For a long time this plant has caused a great deal of disappointment to would-be inventors of machinery for the preparation of its fibre for manufacturing. The machine wanted is one that will clear the fibre of gum and separate it into threads. This part of the work is done by hand in India and China, where the laborers are paid an insignificant sum for a day's work. To do it profitably in this country by hand is out of the question. The material which could be cleaned by one person in a day of ten hours would not warrant the payment of more than a few cents as wages, hence the long and tedious work of developing suitable machinery to perform the operation. Mr. S. H. Slaughter, of Los Angeles, California, who has given much study to the cultivation of fibre plants and to the perfecting of machinery for their manufacture into cloth, has been in this city for some months past, endeavoring to enlist Government aid in the establishing of one or more factories to demonstrate to the people the feasibility of properly preparing the fibre. The inventor claims that the principal difficulties in the way of preparing fibre have been overcome, and that all the infant Ramie industry needs is a lift by the Government. People are slow to invest their money in this industry until it is shown by actual working experience that the project is practicable and profitable.

Much has been written concerning the different kinds of Ramie, and all agree that one of the species outstrips all the others in yielding fibre. It is called *Boehmeria nivea*, a plant quite common in gardens all over the south, having been disseminated widely by the Department of Agriculture for several years. It does not possess much beauty, being a tall Nettle-like-leaved herbaceous perennial, attaining a height, under favorable circumstances, of about seven feet. It is a native of China, and will not endure our northern winters unless it has protection. It has been killed outright more than once during the past thirty years in Washington, so that this may be said to be the northern limit of its hardiness. It is seemingly not overparticular as to soil or situation, and in ordinary seasons, when there is an absence of long dry spells, from two to four crops may be expected. In some recent consular reports it is stated that Ramie cannot be raised from seed. This is a mistake, as there are few plants which yield more seed than Ramie, but it takes intelligent care to raise plants by this method, as the seed is exceedingly small and the seedlings are very tiny for some time after germination. The seed cannot be expected to germinate and grow with the same treatment accorded to most farm seeds. They must be sown under cover in some simple kind of glass structure and carefully tended until large enough for the field. Should the establishing of the Ramie industry become an accomplished fact, it may be that the difficulty of raising the plants from seed will deter cultivators from adopting that method of growing it in quantity, and root division may be the most popular method. The fibre is contained in the long straight stems which rise from the roots, and the crop is fit for cutting when the part nearest the root begins to turn brown. After being harvested and denuded of its leaves, the process of decortication, which is a very simple one, is all that is required of the cultivator before delivering the crop to the factory. The decorticating process consists of breaking and stripping the woody matter from the fibre, and is done by recently improved machinery which was exhibited at work at the midwinter fair in the west. The uses to which the fibre is put are many and varied; it is made into the heaviest ropes and into cloth for every variety of use. It can be used with silk to produce the most delicate fabrics. The cloth made from the fibre is said to withstand more wear and tear than any other.

Botanic Garden, Washington, D. C.

### Hardy Cacti.

To the Editor of GARDEN AND FOREST :

Sir,—A few interesting native species of Cacti are found along the eastern foothills of the Colorado Rocky Mountains. They well deserve to be considered hardy, as they are frequently subjected to forty or fifty degrees of frost without harm, while the earth is bare of snow, and to the trying conditions of almost daily freezing and thawing throughout the winter. During early spring wet snows follow in close succession and keep the ground saturated at a time when so much moisture might seem unfavorable. However, the plants take advantage of this time to fill themselves with water to last during the blooming and fruiting season.

Three kinds of *Opuntias* are common, *Opuntia fragilis* and *O. Rafinesquii*, which are usually confined to plains bordering the foothills, and *O. Missouriensis*, the most showy sort, and found on high rocky ledges or hillsides.

*Echinocereus viridiflorus* is the most common of the globular sorts. It is usually known as Rainbow Cactus, on account of the bright-colored spines. It is found both on the hills and adjoining plains. *Mamillaria vivipara* is a very beautiful species, but is rare in this vicinity. The flowers are red or purple, and each of the long tubercles is tipped with a star of long bright-colored spines. *Mamillaria Missouriensis* is a curious sort, nearly flat, the tubercles mostly upright, with a cluster of white spines at the tip of each. The flowers are yellow and are followed by crimson berries. *Echinocactus Simpsoni* is a tuberculated species, seemingly intermediate between *Echinocactus* and *Mamillaria*. It is very showy at all seasons, and especially while in flower. It is also the largest of our globular sorts. It is densely interlaced with brownish purple, or sometimes yellowish spines. The flowers are rose-purple or pink, usually numerous. *E. Simpsoni minor* is a reduced form found in the high mountains of Colorado, and, doubtless, grows at a higher altitude (9,500 feet) than any other Cactus, latitude being considered. This differs much in appearance from the type, and does not lose its distinctive features after the two are grown under similar conditions at a lower altitude.

In the garden all of these may be well grown on a low broad

mound of coarse gravelly soil, well supplied with decomposed vegetable matter, through which small broken stone may be mingled to good advantage. The soil should be deep and with good drainage at the bottom; this is essential, as stagnant moisture at the roots must be avoided. The surface may be mulched lightly with coarse, hard gravel or pebbles, to keep the rain from spattering the plants with dirt. The bed will increase in beauty year by year, and will require but little care after the first season. The winter effect is also pleasing, and this feature alone should add in no small degree to the popularity of our hardy Cacti.

Boulder, Col.

D. M. Andrews.

### Early March in West Virginia.

To the Editor of GARDEN AND FOREST:

Sir,—Vegetation has started here unusually early, and every bright morning we are delighted by the new beauty which invests our garden. Under a great Oak in a situation unfavorable to the growth of grass, we have massed hundreds of bulbs of Narcissi, Snowdrops, Scillas, Grape Hyacinths and other sturdy early-flowering sorts, and in the grass in the open lawn we hid away Crocus bulbs last autumn, sure of finding them again when the first warm sunshine came, and now every day we are enjoying fresh surprises which nature has prepared for us overnight. Every morning we find more Tulips above the ground, more Hyacinths in the border, more Daffodils everywhere. The early birds are here, too, song sparrows, with an occasional robin, with a few blackbirds, the forerunners of the large congregation which will soon be holding their conference in the Oaks. Bluebirds are here, and Carolina wrens and redbirds are whistling like eager boys. Leaves are unfolding on the Spiræa bushes, the Hazels are hanging out their catkins, the Chimonanthus bushes are adorned with hundreds of yellow fragrant bells, the grass is green, and, in short, April is here a month ahead of time.

Rose Brake, W. Va.

### More About Choke Cherries.

To the Editor of GARDEN AND FOREST:

Sir,—I have never seen the Choke Cherry in this section of New Jersey, but I have seen a great many in Massachusetts, differing largely in size and quality of fruit; all, however, more decidedly astringent, with one exception. While fishing for trout in a brook which flowed through an extensive meadow I came upon one tree which produced fruit in which I could detect no astringency whatever. This was more than forty years ago, and I did not then appreciate the advantages of selecting and improving our native fruits. I do not know whether this tree is still in existence, or whether I could find it if it is, but it is quite possible similar varieties may exist elsewhere, or might be obtained from extended experiments with seedlings.

### Recent Publications.

*Principles of Plant-culture.* Professor E. S. Goff, Professor of Horticulture in the University of Wisconsin. Madison, Wisconsin: Published by the author.

This is an attempt to give students in an elementary form some of the reasons for the ordinary processes of cultivation. It does in reality more than that, and in a chapter on methods of manipulation it explains with some detail the practice of propagating, transplanting and pruning plants, but even here the reasons for each step are carefully presented, so that the work can be done intelligently. As the book is intended for students who have little or no previous instruction in botany, no space or effort is devoted to advanced scientific problems, but, as far as it goes, the little treatise presents to the reader or student a view which is thoroughly scientific—that is, the science of plant-culture is primarily treated, and treated as the basis of the art. Of course, a brief work like this accomplishes its highest purpose only when it is used in class work under the guidance of a trained instructor. An appendix sets forth an outline of the laboratory work which has been used by Professor Goff with his students, and although this contains only half a dozen pages, and is meant to do nothing more than suggest what can be accomplished in this line, nevertheless it clearly indi-

cates that one who has the requisite knowledge and who is apt to teach, can make this study a most interesting one. Experiments, here only hinted at, suffice to show how the mere statements of the book can be vitalized so that they have a living and practical significance. We do not mean that the book is useless without a skilled teacher, for it can be read with great profit by any young person of ordinary intelligence who wishes to familiarize himself with the so-called laws which underlie farm and garden practice, and this syllabus of laboratory work will suggest a good many ways in which he can illustrate the teachings of the book for himself. Of course, to carry out effectively the kind of instruction we refer to, some glass structure is almost indispensable, but a great deal can be done in a sunny window, and we see no reason why a book like this could not be used in certain classes of our public schools, since the only apparatus actually needed would be a few bottles of clear glass, some graduated glass cylinders, a magnifying lens of good power, with needles and forceps and a few greenhouse pots and saucers. Any teacher who knows something of structural botany could lead his class into most interesting fields, and, indeed, a study of the principles of plant-culture could in this way be made the best practical illustration of the science of botany. In an elementary treatise like this it is very difficult to know what topics to neglect, but Professor Goff seems to have been very judicious, both in selecting and omitting. After an introduction, in which a few of the terms which most frequently occur in the treatise are defined, the circuit of plant-life is traced from the first swelling of the seed, through the development of the embryo, the penetration of the root into the damp soil, the absorption, distribution and assimilation of food, until the plant is built up to maturity, and ceases work and rests through the winter. This includes in a brief way all the processes of plant-life as they are carried on in congenial surroundings, and they suggest methods of making and preserving a favorable environment by proper cultivation. But, since the practical cultivator constantly meets adverse conditions, this is followed by a most interesting discussion of the ways in which the plant is affected by unfavorable environment, by a temperature too low or too high, by excessive or insufficient water, by too much or too little light, by an improper food supply and by parasites and weeds. After this are chapters on plant manipulation, and some brief hints on plant-breeding. Future editions will undoubtedly show that the book can be improved, but certainly the plan on which it is conceived is admirable, and no treatise of a like scope that has come under our observation has been carried out with greater success. It ought to prove an efficient help to beginners in agriculture and horticulture, since, if thoroughly mastered, it will insure an intelligent basis for further study.

### Notes.

In his address before the Western New York Horticultural Society, President Barry spoke in high praise of the Jonathan as a winter apple, and a recent issue of *The Country Gentleman* speaks of it as superior in every respect to the Baldwin, and rivaled by few varieties in beauty, flavor or shipping qualities. Its slender growth seems to be an objection to the tree with many cultivators, so that nurserymen have not commended it as they might have done. But it succeeds in a wide variety of localities and it ought to be an excellent apple for the foreign trade.

A correspondent of the *American Florist* writes that the Messrs. Ellwanger & Barry have once more demonstrated that the Crimson Rambler Rose is admirably adapted for winter flowering. Strong two-year-old plants taken up from the field in autumn and potted in seven-inch pots filled with ordinary Rose soil, were full of bloom in mid-February. Many of the flower-clusters were more than six inches through, and their gay colors, with the healthy foliage, made a beautiful show. The plants were pruned back severely before potting, and the young growth pushed out from every eye. The new branches are only from ten to eighteen inches long, stiff

enough to carry the numerous flowers, but arching sufficiently to give the plant a graceful appearance. Ordinary plants carry about a dozen clusters, and they form nice bushy specimens from eighteen to twenty-four inches high and something like eighteen inches in diameter, although they were grown somewhat closely together on a bench and received no extra care.

A writer in the *Orchid Review* states that for half a dozen years he has treated his plants with ammoniacal vapor, which has increased their vigor and improved the color of the leaves of all species of Orchids. This vapor bath has been administered on Monday and Thursday nights every week after the houses have been damped down and the ventilators tightly closed. Soot and lime are used to produce the ammonia, but they are not used dry, since it has been found that there is much less danger of injury to the leaves by the use of a liquid solution which can be spread more evenly and which gives off its ammonia more slowly. A bucketful of soot and half a bucketful of lime are put into a tub with twelve gallons of water, and after being thoroughly mixed the liquid is allowed to stand for three days, when it is ready for use. No care is taken to use the clear liquid alone, but the mixture, thick and thin, is spread over the cindered stages of the houses at the rate of three gallons to a house containing 4,000 cubic feet of air space. The tub is then refilled with water, soot and lime, so that the mixture is always ready in three or four days when needed again.

Every one knows that when seed potatoes are allowed to sprout and the sprouts are broken off, as they often are when the potatoes are kept in a dark cellar, the tuber is perceptibly weakened, the yield lessened and the ripening retarded. The best way to keep seed potatoes is in cold storage, and when thus kept at the Ohio Station they came out sound and fresh, with no sprouts and with unimpaired vitality, even as late as the first of June. It is important, however, that the temperature should never fall below thirty-five, nor should it rise much above forty degrees. In a press circular sent out by the Ohio Station it is advised that the seed potatoes should be shoveled over frequently, as this prevents sprouting to a certain extent where cold storage is not available. Planters are reminded, however, that under certain conditions this sprouting process may be used to advance the early ripening of the crop. If the tubers are placed stem end down in single layers in shallow trays in a light and moderately warm room they will send out short stubby green sprouts which will remain in that condition for weeks, and if the potatoes are then planted without breaking the sprouts they will start immediately.

In one of the suburbs of Dayton, Ohio, an association has been formed for the purpose of beautifying the streets, the unimproved property and the public grounds by proper planting, by promoting a general interest in gardening, and by systematic efforts to abate nuisances and to control the location of houses so far as possible. Lectures are given, with views, to show how house surroundings can be made attractive, and the newspaper reports say that this part of Dayton has shown marked improvement in its appearance. Prizes are offered by the association for the best example of planting in individual grounds, together with the condition of the roadways, gutters, curbs, sidewalks and general appearance of the houses. Prizes are also offered to boys for the best vegetable gardens, as well as prizes open to boys and girls for the best kept back yards, whether planted with flowers, shrubbery, climbers or grass. Photographs are to be taken of the examined gardens, with particular sections and decorations of the streets entered in competition, and a neat pamphlet has been published containing views of the prize-winning grounds last year, and also embodying good advice about trees, shrubs and climbers, with the methods of planting and caring for them.

One of the useful botanical discoveries made by our experiment stations is that which traced the source of the potato scab to an infinitesimal germ that feeds on the surface of the tuber, and from this broadening of our scientific knowledge came the practical advice to use corrosive sublimate, which would kill the fungi on the tubers without injuring their growth. The remedy was so cheap and easy that many large growers have adopted this treatment as a regular part of their farm economy, but the poisonous nature of this fungicide has prevented its general use. Dr. J. C. Arthur, of the Purdue University Experiment Station therefore confers an added benefit upon farmers by the announcement that the new antiseptic known as formalin, which is not very expensive, and which is likely to become cheaper as it is better known,

makes an efficient remedy for the potato scab, while it is not poisonous. Eight ounces of formalin are added to fifteen gallons of water. The seed potatoes are soaked in the solution for two hours, and then they are cut and planted as usual. Since formalin is not corrosive, it can be used in any kind of vessel, and not being poisonous no particular caution needs to be observed, except that it will make the hands smart where there are any abrasions of the skin and its fumes irritate the eyes and throat. Further information about formalin and its uses as a fungicide are promised in a bulletin which will be issued by the station in a short time.

In a letter to *The Fruitman's Guide*, of this city, from a London wholesale dealer in fruits and vegetables, an interesting variety of products is noted in that market in the latter part of February. Baldwin, Greening, Russet and Golden Russet apples came from New York and Maine, and in addition Nova Scotia was sending Northern Spies, Cranberry Pippins and Nonpareils, with Newtown Pippins from California, besides apples from France. The supply of Easter Beurre pears was from California, and Italy also furnished varieties of the same fruit, while new crop Bartlett pears, known in the English markets as Williamis, were coming from the Cape of Good Hope. Packages of a dozen of the latter fruits, of exceptionally fine quality, sold at wholesale at \$2.25 a package. As we stated a fortnight ago, peaches were being received from the Cape of Good Hope, during the summer season of that southern country, and new crop grapes. The demand for oranges was supplied by consignments of this fruit from Spain, Palestine, Italy and California. Tangerines, lemons and bananas were in regular supply, and 18,544 pineapples came from the Azores during the current week, from thirty-seven cents to \$1.00 being realized for each of the fruits in wholesale lots. New potatoes came from Egypt, Algiers and the Canary Islands, and new asparagus from Spain and France. The choice variety locally known as French Giant sold at the extremely high price of \$3.00 to \$5.00 a bundle, and slender green stalks, about thirty-two to a bundle, for \$1.00 to \$1.37, while twenty stalks of this vegetable from Spain brought from fifty to sixty-two cents. New cauliflower was provided by Italy, France and the west of England, and there were, besides, abundant supplies of turnip tops and other greens at moderate prices.

Last year the Agricultural Experiment Station of Rhode Island made systematic tests with garden seeds to ascertain their germinating power. Of 233 samples twenty contained three or more poor seeds for every good one, and of twenty-three others more than half of the seeds would not sprout. In continuing the examination 150 more samples have been studied, and the vitality of thirty-four of these last fell below fifty per cent., which means that a purchaser of seeds would receive in most cases less than half of his money's worth in seeds that would grow. The results vary astonishingly. In some of the samples less than ten per cent. of the seed germinated, while in others more than ninety per cent. were good. If there were any uniformity in the percentage of good seed a gardener might know how thickly to sow it, since too many plants in a given space are as disastrous to a crop as too few, but no one can guess how many onion seeds he ought to sow when twelve per cent. in one sample grow, and eighty-six per cent. in another sample. In twenty-three cases seeds bought from the same dealer show a lower vitality this year than they did last, which suggests the possibility that some of this year's seed may have been taken from last year's stock which was held over. At all events, the results indicate that too much ought not to be taken for granted concerning the vitality of seeds, especially when they have been carelessly stored for months. A man who plants bad seed not only loses the money he pays for it, but he loses the use of his land, the fertilizers and the labor wasted in trying to obtain a crop which he never grows. This bulletin well adds that with the struggle now going on to keep the cost of production below the market value of crops the vitality of seeds becomes an important question. Seed of low vitality tends to curtail the yield of a crop, not only because the entire area of the land is not utilized by it, but because it takes crops from such seed, in many cases, longer to mature on account of the lack of vigor in the young plant, and these two considerations so influence the receipts from a crop that it may not be sufficient to meet the expenses of growing it. The purchaser, therefore, ought to have some assurance that his seed is fresh and that it is properly kept, and the only way that such a guarantee can be had is in some agreement between the buyer and the seller by which the latter will regularly test his seed in bulk and furnish each purchaser with a truthful statement of the result of the test.

### Congress and the Forest Reservations.

TWO weeks ago we described in these columns the thirteen forest reservations established on the 22d of February by President Cleveland on the recommendation of a Commission appointed by the President of the National Academy of Sciences, which has been studying the western forests during the past year. Late Sunday night, February 28th, the Senate of the United States, on motion of Mr. Clark, of Wyoming, proposed the following amendment to the Civil Sundry bill, one of the great appropriation bills then under discussion: "And all the lands in the states of Wyoming, Utah, Colorado, Montana, Washington, Idaho and South Dakota set apart and reserved by Executive orders and proclamations of February 22d, 1897, are hereby restored to the public domain, and subject to settlement, occupancy and entry under the land laws of the United States, the same as if said Executive orders and proclamations had not been made." The two reservations in California were not included in this amendment at the request, as we have been informed, of the senators of that state. Possibly Colorado may have been written instead of California, as no reservations have been established by President Cleveland in the former state.

The Senate, deceived by the false statements of the representatives of western mining and lumber companies who became the champions of this amendment, passed it without hearing a single word of protest. The following day the Chairman of the House Committee on Public Lands prepared an amendment to the Senate amendment providing that the Secretary of the Interior be authorized to make sales of timber on any forest reservation, now or hereafter proclaimed, for mining and domestic purposes, and to make all needful rules and regulations for their management and protection; opening all the forest reservations to the location of mining claims, authorizing the opening to settlement of all lands in the reservation more valuable for agricultural purposes than for forest uses, after inspection by a person appointed or detailed for that purpose by the Secretary of the Interior, actual restoration, however, being made only after due publication or by proclamation of restoration by the President based upon the recommendation of the Secretary of the Interior; giving to prospectors

and mineral claimants free access to all forest reservations for the purpose of prospecting, locating and developing mineral resources, and according them the right to acquire titles to mineral lands in the same manner as for other mineral lands in the United States. The President is further authorized in this remarkable amendment to modify at any time any executive order that has been or may be made establishing any forest reservation for the purpose of reducing its area or changing its boundary lines, and is authorized to vacate altogether any order creating such a reserve. This amendment, which was introduced into the House Tuesday afternoon, March 2d, was carried by a large majority, no one opposing it but the representatives of two or three of the western states in which reserves are located, who favored the adoption of the Senate amendment.

The House amendment, on the whole, was more to be dreaded than the proposition of the Senate to annul the proclamations of February 22d, because it meant the ruin not only of the new reserves, but of the seventeen million acres of forest preserved by earlier proclamations. It empowered the Secretary to protect and utilize the reservations and to sell timber from them and to open them to the location of mining claims. No appropriation of money, however, was made to enable him to protect and manage the reserves, although he was permitted to use for this purpose, at his discretion, any part of the \$90,000 appropriated for the general care of the forested portions of the public domain. This appropriation is notoriously too small for the purpose for which it was originally intended, and it is evident that no part of it could be spared for additional protection to the reservations. The Secretary was authorized to sell timber from the reservations, but there are no agents in his department who have the technical knowledge and training needed to manage this business, and until a responsible forest organization in the Interior Department can be got into working order the rights of the Secretary of the Interior to invade the reservations should be carefully limited.

Nor is it safe with the present methods and organization of the Interior Department, and the existing lack of knowledge of the topography of the reservations, to trust any ordinary civil agent of the department to decide what part of the reserved lands shall be thrown open to entry. The actual taking of the land from the reservations is to be done by the President or Secretary of the Interior, but this action must necessarily depend entirely on the report of some subordinate who will be subjected to temptations which the agents of the great western mining and lumber-making companies know only too well how to make effective to modify the independent judgment of Government officials; and it is safe to predict that the enactment of such an amendment would, in the course of twenty years, strip the reservations of their most valuable forests on the plea that the land which produced them was valuable for agriculture. More dangerous even is the authority giving to prospectors and mineral claimants free access into the reserves without any control of any sort by anybody. The first thing a prospector does when he enters a wooded country to look for minerals is to set fire to the woods in order to expose the rocks, and the denser and more valuable the forests the more anxious he is to burn them off. A large proportion of the forest fires in the west are set for this purpose, and hundreds of thousands of acres of forest land have been ruined by prospectors, the smoke of whose fires obscured the sun for months last summer in the Kootenay mining region of northern Washington and southern British Columbia.

In final conference both the Senate and the House of Representatives receded from their positions, and when the Civil Sundry bill finally reached the President it contained only the following amendment concerning the forest reservations:

"The President is hereby authorized at any time to modify any executive order that has been or may hereafter

be made establishing any forest reserve, and by such modification may reduce the area or change the boundary lines of such reserve, or may vacate altogether any order creating such reserve." This amendment would probably have proved harmless, for the President has already this right, although this fact has been disputed.

The bill with this amendment did not receive the President's signature, so that the status of the reservations is exactly the same as it was before the passage of the Senate amendment on the 28th of February.

It is a proposition which admits of no argument, that the forest reservations cannot be used exclusively for any particular class of the community; they belong as much to the east and to the south as they do to the west. They are part of the public domain, and it is for the interest of the whole country that they should belong to the nation. But these reservations must be managed so that they shall continue to preserve the flow of rivers protected by their forests; their trees must be cut to supply lumber, fuel and fencing material; mineral deposits must be sought for and mined within their boundaries; and all land really valuable for agriculture must be taken from them and opened to settlement. Unless the reservations can be made to play their part in the best permanent development of the country, there is no justification for their existence, and sooner or later they must be abandoned. But there is now no organization under the Government which can be trusted to make rules for the wise management and development of the reservations, or which can carry out such rules after they are made, and until Congress authorizes the establishment of a national forest service and the Secretary of the Interior can organize it, the reservations should be strictly guarded against invasion of every kind, unless the country is prepared to witness the destruction of one of its most valuable possessions.

There is great danger, however, that another attack will be made on them in the extraordinary session of Congress which met on Monday, but the protests which have been raised in the press all over the country against the action of the Senate show that a new attack, made on them by men who seem to believe that the national domain is their private property, to be used in any way that will fill their pockets fastest, will meet with serious opposition.

We cannot deny the gravity of the situation. Many men honestly believe that these great reservations are unnecessary; they will certainly be opposed by every man in the states where they are located who wants to cut timber on the public domain without paying for it, or desires to secure a title to Government timber-land. Every miner who wants to burn over the country to facilitate his prospecting, or wants to timber his mine at the cost of the nation, and every sheep man who wants to pasture his herds on the public domain, to which all sheep men now seem to believe they have acquired a vested right, will oppose forest protection in every way in their power. These men are noisy, active and well organized; they have great influence in Congress, where their claims will be loudly and persistently pressed, and only the expression of the calm judgment of the country can save the situation.

#### Ceanothus in the Landscape of the Sierra Nevada.

THE greatest charm of the landscape in the lowest foothills of the Sierra Nevada is the "Mountain Heliotrope," the *Ceanothus tomentosus*, Parry, in flower on May-day. It is interspersed with the all-covering *Adenostoma fasciculatum*, or Chemisal, and seems to gain additional charm through association with *Baccharis consanguinea* with its bright green and varnished foliage. It is but seldom that we find a shrub of this Mountain Heliotrope which has developed naturally. Like the trees in the forest, it is crowded, and the sparingly foliated limbs have to reach light as best they may and secure room for its sun-loving bloom. In all my rambles I have never

found a shrub showing other than rich blue flowers, although there is a variety with flowers of a clear and pure white.

The term "Chaparral" is often applied to the shrubbery on our hillsides, no matter whether such is composed of Manzanita or any other growth, but by the people who live here it is applied to only one *Ceanothus*, and that is *C. cuneatus*, the pest of uncultivated land. It ranges from 750 feet elevation up to 2,500 feet, but will occasionally creep into higher zones, provided warm currents favor its growth. It is, therefore, a companion of *Pinus Sabiniana*, the Nut Pine. A common but erroneous belief is that it grows on good land only. Such is not the case. It will grow on rocky as well as deep soil, provided only that it gets plenty of sunshine. It will clothe hillsides for miles and give them the grayish Nile-green tint which they always present to the distant beholder. At the time of flowering, in the last week of March, this color changes and the whole seems cream-white from the millions of minute flowers which they produce on the extremity of every limb. The inside of these much-branching low-limbed shrubs appears dead and has been well compared to a bundle of strands of barbed wire. Seedlings grow up by the million, and all appear equal and well fit to struggle for existence with their neighbors. Wherever man has done any cultivating, cleared an old woodroad, cut a trail, plowed a furrow in years past or still keeps cultivating it, the Chaparral follows him, like the Nettle or Chickweed.

At the mean height of this Mountain Heliotrope belt, about 1,500 feet, we find a new species, a charming shrub, *Ceanothus Californicus*, Kell (*C. integerrimus*, H. & A.) More tender in appearance as well as in texture, it also chooses a more lovely companion in its zone, the bright green *Libocedrus*. People call it Deerbrush, as it offers good browse for the deer when such are driven down by heavy snowfalls in higher altitudes. As pasture is poor all through the Sierras, cattle partly live on Deerbrush, and it withstands well such abuse. While ten feet is the average height for this shrub, I have seen trunks of old, well-protected specimens with a diameter of eight inches. The foliage is very dark green, even when tender and new, and the limbs add greatly to the color, as they remain green for years, and then only turn silvery gray. Their large trusses of slightly cream-colored flowers caused the name of Lilac to be given to them, and we find these plants even in the gardens about the mountain homes in spite of the tendency to seek foreign shrubs and flowers. The blooming period of this so-called Lilac is very long; in fact, it has two distinct periods. The beginning of May sees the first bloom open, and as late as October and even November their flowers may be gathered. These are developed on shoots which lengthen the summer growth, and often on branches bearing many seeds ripe enough to drop out. This plant prefers northern slopes of creeks and gullies, and blooms best wherever the sun gives it most light. The texture of the leaves is thick, and they are evergreen like the other species mentioned. If growing in thickets, as it does very often, it has straggly limbs, like any other *Ceanothus*, yet under free development it is a very effective shrub and lends character to miles of riverside slopes.

The earliness of its bloom and the lowness of its occurrence bring this species in contact with the blue bloom of the Mountain Heliotrope, and I remember, with renewed pleasure, the surprise and delight I had when coming across a very beautiful hybrid between these two species. I found it near Clinton, on the rough banks of a mined-out region, almost deserted, though once populated by thousands of miners. This hybrid proved in every detail that the mixing of blood is almost always productive of a development of the characters of both parents. The trusses were far larger, taking this characteristic from *C. Californicus*, while they were more conical, a trait derived from *C. tomentosus*. Their color was a tender lavender, clear and pleasing. The shrub was more robust than *C. tomentosus*, and yet not so thickly branched as *C. Californicus*.

nicus. As it stood, unhampered by other shrubs, it was a perfect specimen, well worth an honored place in our arboreta. I have not found it since, and could not procure any seed at the time.

As we climb upward in our exploration after *Ceanothus* in the Sierra, and follow the road of the stockmen, who drive thousands of cattle and sheep to the tender grass of the highest altitudes, we notice a low shrub in the way which has apparently survived the trampling of the herds. It is also a *Ceanothus*, rather two of them, and both lying close to the ground, spreading like a trailing vine, slow of growth, and reaching but about three inches in height at the centre of growth. I never saw either in flower, their blooming season being early in April, when the roads at this height of 4,500 feet are impassable for wagons and too distant to reach on horseback. One species, *C. prostratus*, Benth., is an exact counterfeit of *C. cuneatus*, of the same pale green, twisted in wood and thorny to the touch. The other, *C. diversifolius*, Kell., is the counterpart to *C. tomentosus*, its foliage soft and its limbs green like those of *C. Californicus*. They trail along and cover the ground where neither grass nor flower appears on mountain-ridges, and make room only for the all-covering Mountain Misery, *Chamæbatia foliolosa*, on lower ridges, where more moisture and thicker shelter favors the growth of the latter.

The last *Ceanothus*, *C. cordulatus*, Kell., we find just as we leave the region of the Sugar Pine. The herder thinks about snow at the time he sets out with his herd for climbing the mountains in early June and sees it over yonder, where he is aiming. He looks close at hand upon low, spreading shrubs all white with bloom, set in a thicket of spines, clothed with pale green leaves, and this *Ceanothus* he naturally calls Snow-brush. These shrubs, the bark of which remains Nile-green almost all the year, develop in a very regular bell-shaped form where they have any chance, but they are usually pressed down by the heavy snowfall for many months in the year. They resemble *C. cuneatus* in their make-up, and like it they will cover every inch of a hillside if open spots with fairly good soil are reached, decaying lava giving them a favored ground. I well remember the trial I once had when struggling through their matted thorns in search of *Lilium Washingtonianum*, which grows among them, standing like the candles on an altar above the green cover spread for them. This Snow-brush grows at an altitude of from 5,000 to 6,000 feet, just where the cattlemen reach a ridge which offers them no feed at all. The sheep ruin everything in the way of growth, and this thorny, impenetrable Snow-brush protects the only flowers we find in that region. The white Lily is rivaled by the beautiful spike of *Epilobium angustifolium*, and in well-defended shelters we gather the bright *Erysimum asperum*, and the only grass which escapes the ravaging sheep, the pretty *Sporobolus gracillimus*.

#### Conifers on the Grounds of the Kansas Agricultural College.—IV.

##### THE SPRUCES.

THE Douglas Spruce, *Pseudotsuga taxifolia*, has not been planted in great numbers, but specimens are to be found in many different locations about the grounds, and it seems to thrive in all. The starting of the trees is attended with some little difficulty, but, once established, it has uniformly done well, and I doubt if, on the whole, it is much more tender than some of the Pines which have the name of exceeding it in hardiness. Certain it is that three Douglas Spruces, moved in January, 1896, leaving a large ball of earth attached to the roots, and set near Science Hall, have all lived and are growing well, while out of six Scotch Pines moved at the same time to the same location and treated in the same way, two have died. Similar good results have attended the moving of the Douglas Spruce to other parts of the grounds in other years, though care has

always been exercised that the trees should be set in the best manure possible and that the roots should not become dry, a thing which seems to be more prejudicial to conifers than deciduous trees.

All the Douglas Spruces on the grounds are from two lots set in nursery rows in the springs of 1887 and 1888, being then about 16 inches in height. Since then most of them have been moved to different parts of the grounds, but eleven trees still stand in the old nursery rows, and these average as follows: Height, 9 feet; diameter at the ground, 3.92 inches; at 1 foot, 3.3 inches, and at 2 feet, 2.8 inches. The largest tree of the lot is 11½ feet tall, with a diameter of 5¾ inches at the ground. It will be remembered that the tallest Scotch Pine of the lot planted in 1891 measured 11 feet in height, so that, counting the trees the same age at setting, the Scotch Pine has made practically the same growth in five years that the Douglas Spruce has in seven years. When we remember that the Scotch Pine is one of the most rapid-growing of the conifers, this is not a bad showing for the Douglas Spruce, and certainly it ought to be planted if only for its beauty.

As beautiful as the last-named tree, almost more beautiful, is the Colorado Blue Spruce, *Picea pungens*. It has been planted to about the same extent in the grounds, and is rather more hardy, though of slower growth. Specimens with foliage of the pronounced glaucous shade form only a small percentage of the seedlings, but the trees are always handsome, and some persons prefer the darker shades ordinarily considered less desirable. The characteristic beauty of the tree is but little affected by drought or winter, and, once established, it seems to thrive in the worst seasons of this section of the state. Twelve trees set in the nursery rows in 1888, being then about 12 inches high, and allowed to remain there, now average 5½ feet in height, 3½ inches in diameter at the ground and 1.96 inches at 2 feet. The tallest tree is 7 feet. A single tree set in 1887 in a similar location now measures 8½ feet high, with a diameter at the ground of 3¾ inches, and at 1 foot about 3⅜ inches.

The White and Norway Spruces, though not very generally planted, have shown many desirable qualities. The White especially has done very well, transplanting easily and thriving in almost any location about the grounds. The tendency which the Norway has to become ragged as it gets older, especially if crowded in the least, is rather a serious objection to it, and it is not so handsome a tree as the White, even when well grown, though they are similar in many respects. The Norway, moreover, is much more susceptible to unfavorable climatic conditions. It is the more rapid grower of the two, a growth of twelve to eighteen inches from the terminal shoot not being uncommon in favorable locations and among trees that are well established, while in the White the terminal growth will range from six to ten or twelve inches under similar conditions. Most of the specimens on the grounds are too young for their measurements to be of interest, but a single specimen of the White Spruce, now about twenty years old, measures as follows: Height, 27½ feet; diameter at the ground, 10 inches; at 2 feet, 8½ inches, and at 6 feet, 7½ inches.

#### The Arrangement of Flowers.—III.

##### THOSE SUITABLE FOR BOWLS.

ONE of the principal ways of arranging flowers is in bowls, and this is particularly suitable for many garden and wild flowers, such as azalea, scarlet sage, sweet clover and daisies. It is the easiest arrangement, and the only one in which it is possible to use handfuls of flowers at once. But this lazy method has its limitations. In a mass of *Azalea nudiflora*, for instance, it is better that one section should be of the darkest blossoms. They grow in this way, one bush all of deep pink flowers, while the next is covered with those of lighter color. Dis-

posed in this way in masses of distinct tones the collection will have a beautiful shaded effect.

It is well to place some smaller vases inside the bowl, as a finger-bowl, and inside of that again an ordinary glass. This enables one to place the flowers exactly where it is wished to have them, and they are also kept in place. As autumn advances, more vivid coloring is everywhere seen in plant-life. We lose from the garden such flowers as the pale forget-me-not and garden pink, *Dianthus plumarius*, and red and yellow flowers predominate, as though Nature wished to give us her most brilliant colors before reducing us to the sombre tints of winter. Huge bunches of golden-rod and sunflowers, *gaillardia* and *coreopsis*, are appropriately used to decorate the halls, and great clusters of bright red crab-apples brought in from the orchard, while the dining-table is decorated with a mass of showy *Phlox Drummondii*. There are many yellow flowers, as *gaillardia*, *coreopsis* and *calendula*, which combine effectively with other colors. The double yellow *calendula*, for example, shades from pale to deeper and unusual tints. These flowers look particularly well combined with bright blue corn-flowers, *Centaurea cyanus*; brighter yellow flowers would be too vivid for the blue, but this combination seems to suit the *calendulas*. *Gaillardias*, with their deep red centres, show to good advantage combined with deep red flowers, such as those of *Monarda didyma*, and the yellow petals are thus brought into good relief. Red and yellow well combined make a beautiful effect. Nature teaches us this in all her autumn coloring, and it seems reasonable to adopt the same combination for cut flowers also.

Among the flowers which are suitable for arrangement in bowls none are more difficult to dispose pleasingly than *nasturtiums*, and it is easy to make them look stiff. The ordinary bowl is useless for them, as the stems are short. The leaves wilt quickly, and altogether these richly colored flowers are most satisfactory when in the garden. *Baby's Breath*, *Gypsophila paniculata*, has an insignificant, fine little white flower that can hardly be called pretty and has almost no perceptible odor, but it is indispensable. These flowers are carried on almost invisible needle-like stems, and with a spray or two of this in a vase the long-stemmed flowers will stand in exactly the position that is wished, and a delicate feathery effect is given to the arrangement. The foliage is a soft shade of green. The tiny white blossoms are beautiful as a part of the combination, or a small spray may be used in the centre of the bowl to hold the flowers erect and not show at all in the finished arrangement. With *nasturtiums* it is especially useful. It should be placed in the bowl first, and the *nasturtiums* added on the shaded scheme of first a cluster of dark flowers and then of a harmonizing tint, until the effect is a gorgeous rainbow coloring and not at all of a patch-work.

To sum up, in arranging flowers they should be made to look as much as possible as they do in nature. Tall flowers should be arranged in tall vases and short flowers in shallow ones; dainty flowers in a delicate way, and the more solid ones in masses; and the effect should always be to bring the flowers into prominence, and not the vase.

Rangeley, Me.

*Dorothy Root.*

## New or Little-known Plants.

### *Cornus asperifolia*.

THIS shrub of the western and southern United States appears to be rare in gardens, although it has been cultivated for a dozen years in the Arnold Arboretum, where it has proved perfectly hardy and one of the most distinct and desirable of the American *Cornells*. *Cornus asperifolia* is a shrub with erect stems, sometimes attaining a height of fifteen feet, reddish brown and mostly pubescent branches, slender rough-pubescent branchlets, ovate or oblong leaves, acuminate, with long or short points, scabrous above and whitish and soft-pubescent below;

white flowers in ample, open, flat cymes, and white fruit borne on bright red pedicels. *Cornus asperifolia* is distributed from the northern shores of Lake Erie to Minnesota and Nebraska, and southward to South Carolina, Florida and Texas, but is most abundant in the states west of the Mississippi River.

The figure on page 105 of this issue, which we believe is the first portrait of this plant which has been published, is the reproduction of a drawing made by Mr. Faxon from a plant cultivated in the Arnold Arboretum.

## Cultural Department.

### Early Spring Flowers.

MR. WATSON'S letter of last week reminds me to report on the flowers of this debatable season, which is not winter and less than spring. One never tires of the dainty beauty and fragrance of the *Snowdrops*, and it is an annual surprise to watch them boldly brave the rigors of the winter. They were formerly associated with the encouraging idea that another season of growth was commencing, but the edge has rather been taken off that sentiment, for we now have *Snowdrops* in the garden from September onwards, and there is no time during the half year when blooms of these may not be found making such progress as the elements may permit. There are quite two-score clumps of *Snowdrops* under various names in my garden. Many of these are well determined and distinct kinds, and many there are whose labels are geographical queries, as they bear names only of unheard-of places where they were collected, mostly by Mr. Whittall, whose loving labors have added so many good kinds to our garden. Most of these strangers prove to be forms of *Galanthus Elwesi*, but one grows them always with the pleasant anticipation that among them will be found some rare gem. If rapidity of increase and perfect adaptability to the usual garden conditions are tests of greatest value, I quite agree with Mr. Watson that *G. nivalis* is the best *Snowdrop*. While small-flowered, it is as pretty as any of the family. It is the only *Snowdrop* in my collection which forms thick clumps of bulbs and increases rapidly in any position. But there is a wealth of variety and distinctness in the family, and mere difficulty of cultivation will scarcely deter one in such a promising field. Mr. Whittall's *Cassaba* variety of *G. Elwesi* is a bold, distinct flower (one of the largest) on strong scapes. The *Aidin* variety scarcely holds to its original promise, but among the bulbs I was fortunate to find a few with trim flowers and some nice colorless forms—that is, nearly white, the usual green of the ovaries and inner segments reflexed with a slight glow of yellow. *G. Ikariae*, with its shining, broad scilla-like leaves, is one of the most distinct *Snowdrops*, but has not made much progress here. The leaves seem more affected by hard conditions than those of the other varieties. Of the boldest or large-flowered *Snowdrops*, perhaps the most satisfactory is *G. nivalis Atkinsii*. The *Melville* variety of the same species is equally bold, but has an unsatisfactory tendency to produce extra petals, destroying the symmetry of the flowers. Mr. Allen's seedling *Charmer* is another beautiful kind with great purity of color.

Of the more common kinds the Italian form of *Galanthus nivalis imperati* is very pleasing, with long pointed buds. This form of bud, which is owing to narrow outer petals, seems to me distinctly more pleasing than the globose forms which one finds among the *G. Elwesi* and in such forms as *G. robustus*. *G. Fosteri* is a highly esteemed kind which has never done well with me, and *G. plicatus*, the Crimean *Snowdrop* with folded leaves, refuses to stay at all. All the *Snowdrops* are handsome, except the double-flowered *G. nivalis* and the odd horned one, *G. Scharlokii*. This has two horn-like growths, produced by splitting of the spathe and the flower, which is short and is blotched with green markings. The *Elwes Snowdrops* are now so available at a reasonable rate that they should be planted largely, though they do not always increase very well. Perhaps positions under deciduous trees are the most satisfactory, they naturally growing in such places.

The first *Crocus* of the season is usually the rosy *C. Imperati*, but this is not usually as reliable in the garden as *C. Susianus*, the golden color of which is very acceptable at this bleak season, when high colors are very rare. There are other yellow *Crocuses* in flower now, dainty beauties, but they are nameless.

One of the most satisfactory flowers of the season is the *Taurian Squill*, introduced by Mr. Whittall a few years ago,

Fig. 13.—*Cornus asperifolia*.—See page 104.

1. A branch of a flowering plant, natural size. 2. A branch of a fruiting plant, natural size. 3. A flower, enlarged. 4. A fruit, laid open transversely, enlarged.  
5. A stone, enlarged. 6. A winter branchlet, natural size.

and now known as *Scilla Sibirica multiflora*. The natural habit of this flower is so well fixed that it still continues to vie with the Snowdrops for first place. The flowers are brighter in color than the typical *S. Sibirica*, which follows it in flower, and they are very freely produced. A good-sized colony of these plants is about as effective as anything of this season.

All these flowers, though so frail, seem quite happy in the hard conditions under which they have to struggle in an American winter, with its daily changes, which, it is to be hoped, are not as trying to them as to mankind, but my sympathy is always excited toward the early Irises, which often only appear to be buried under the snow. Experience has

shown me, however, that this sympathy is misplaced, for these apparently fragile flowers will brave snow and storms as sturdily as the Snowdrops. *Iris Bakeriana*, quite the prettiest and daintiest of these flowers—in fact, among the choicest of all flowers—has sometimes had its season prolonged in my garden because its flowers were frozen in position so rigidly that they could not change. These little bulbous *Irises* must have care in the garden or they will fail to make strong new bulbs. Professor Foster recommends that they shall be often lifted, which seems sage advice. They are all hardy except *I. Histrio*, which is unreliable, and may or may not survive. It has flowered here, but usually a late freeze after the leaves are well grown will finish it. However, there are others just as good, and there are none of the section which are bad. It is well to grow, say, *I. histrioides*, *I. reticulata cyanea*, *I. Foster*, *I. Krelagii*, *I. Kolpokowskyana*, *I. Danfordiæ*, etc. My earliest *Iris* this year was a particularly small form of *I. reticulata* from Harpoot. These *Irises* are easily increased from offsets and seeds, if one has the patience. The seeds will germinate freely in about twelve months from sowing. The seedlings should be kept in the pans till the bulbs are fairly formed, and in another year they will make blooming bulbs.

Grape Hyacinths are also in evidence, the dark purple kind, which is a gloomy flower. Later we shall have the more cheerful *Muscari azureus*, which is a real blue flower, which, with another celestial-blue, *M. Szovitsianus*, and the white variety of *M. botryoides*, seem to be the best of these rather pretty, if dumpy, flowers.

Life is active in the garden, but, aside from these flowers, the only color is found on a few *Cyclamens*, whose red flowers are small, but striking. Altogether these flowers do not make a great impression of color in the prevailing wet desolation of March, when the garden is at its worst.

Elizabeth, N. J.

J. N. Gerard.

#### Notes on Ferns.

THE regular cleaning and repotting of Ferns should be attended to when the new fronds push up in spring. If potting is done too early there is some risk of the new soil becoming sour in the case of delicate-rooted species, and if this occurs a good start is seldom had. Some of the strong-growing kinds, as some of the *Adiantums*, will bear the removal of all the old foliage before the new growth has started, but, unless the plant is infested with scale or other insects, I prefer to leave the old fronds on the plant, or, at least, all that are in fair condition, until the new growth is fully expanded. A stronger growth is thus secured.

Large specimen plants do not need repotting every season, and a top-dressing in spring and some extra stimulants during the summer are all that is necessary. Elaborate mixtures of compost are not required for the majority of strong-growing Ferns, though necessary for some delicate species. A light, fibrous loam, moderately enriched with dry cow manure is suitable. The house in which the Ferns are grown should be kept closer for a few weeks after repotting, and shaded, for while a reasonable amount of light is required to develop foliage of firm texture, too much sunshine will bleach the Ferns and thus destroy one of their greatest charms—the deep and restful green that is so characteristic of many species.

The watering of the newly potted plants also needs care, for too little is quite as injurious as too much. The main object is to keep the soil in a moist, but not sodden, condition, and thus tempt the tender young roots to further activity.

*Adiantum Farleyense* sometimes has a reputation for fickleness of growth that this noble Fern does not deserve. The mistake is made of trying to grow it in poor soil, whereas the soil best adapted for this variety is three parts strong turfy loam and one part of fine dry cow manure well mixed through the loam. In such soil, and placed in a shaded house with a temperature of seventy degrees, I have grown *A. Farleyense* from a fair plant in a two and a half inch pot to a good, well-furnished specimen in a ten-inch pan, and with a spread of more than two feet, within one year from the time of the first shift.

The much-advertised so-called Boston Fern, a handsome form of *Nephrolepis exaltata*, also makes remarkable progress in a strong soil, in common with the other strong-growing species of this same genus.

A few cool-house Ferns will give much satisfaction where the facilities are not adequate for a complete collection. The *Gleichenias* are prominent among these, and are worth all the care they need. *G. flabellata*, *G. dicarpa* and *G. dichotoma* are

three of the best types, and can be grown well where a temperature of forty-five degrees is maintained during winter.

Special cultural directions for *Gleichenias* have been given in GARDEN AND FOREST in former years. But it may be well to repeat that well-drained and rather coarse soil is preferable, and pans are preferable to pots, because these plants are largely surface-rooting.

*Pteris scaberula* and *Hypolepis distans* are readily obtained and are highly satisfactory for the cool house, though both these Ferns are nearly or quite deciduous, according to the conditions under which they are grown. Another charming Fern for the cool house, notwithstanding its deciduous habit, is *Asplenium Goringianum pictum*. The foliage is not only very graceful but prettily variegated. For large specimens *Woodwardia radicans*, *W. orientale* and *Todea barbara* are all excellent, while *Cyrtomium falcatum*, *Camptosorus rhizophyllus*, *Fadyenia prolifera* and some of the many *Polypodiums* add singularity and variety to the collection.

The worst pest to which the cool-house Ferns are liable is the thrip. This insect multiplies with great rapidity during our hot summers, but with proper care as to moisture, both at the root and in the atmosphere, and careful examination of foliage from time to time, serious injury from this cause may be avoided.

Holmesburg, Pa.

W. H. Taplin.

#### Erythroniums.

I CONFESS myself a lover of *Erythroniums*, or Dog's-tooth Violets. They blossom when flowers are scarce, and the many varieties are in bloom during a long time. *Erythroniums* are unexcelled among early-flowering plants for beautiful foliage and flowers in which grace and delicately beautiful tints are happily combined. The plants are quite hardy, and if their needs are understood are quite easily grown.

*Erythroniums* are woodland plants and need some shade to develop the leaves and stems. Partial shade by trees will answer. I give my beds a lath shade. I have for several years been experimenting with soils for them. They are woodland plants, and, while often found in heavy soils, make better growth in a soil of rocky debris mixed with mold. Much of the charm of Dog's-tooth Violets is in their large leaves and tall slender stems. Rocky debris has not been available, and I have tried several substitutes. Composts of rotten grass and well-fined manure soon packed. I also experimented with old pine sawdust with good success, but have discarded all for a soil of one-half to one-third half-rotten spent tan-bark with sandy loam. Our tan-bark here is the bark of the Tan-bark Oak, *Quercus densiflora*, and is ground at the tannery. This gives a soil rich in mold and always loose and porous. It suits the needs of *Erythroniums* exactly and answers well for many other bulbs.

*Erythroniums* should always be planted early. With few exceptions, the bulbs are not good keepers after fall, and the sooner they are in the ground after the first of October the better. I plant them so that the top of the bulb is about two inches from the surface. The drainage should be perfect. With these essentials of shade, drainage and a loose soil, success is very probable. Although quite hardy, a heavy coat of leaves, such as nature protects them with in their woodland home, would probably be a wise precaution in cold climates. They do not seem to have any peculiar disease, and growing and flowering as early as they do, artificial watering is not necessary.

In the region including the Rocky Mountains and the country westward to the Pacific, fifteen forms are now known, classed as species and varieties. A more charming group of bulbous plants does not exist. Their leaves show a variety of mottling, and in the flowers delicate shades of white, straw-color and deep yellow, deep rose, pink, light and deep purple, are represented. To describe all of these forms so that even a thorough botanist could readily identify them by the descriptions, would be difficult, but in the garden each has some charm of leaf, of tint or of form, which endears it to the possessor.

In their native homes they grow throughout a wide range as to climate and altitude, and in cultivation they maintain their seasons, so that the display which is opened by *Erythronium Hartwegii* with the Snowdrops and earliest *Narcissus*, is closed by *E. montanum* and *E. purpurascens* when the others have flowered and become dry.

*Erythronium Hartwegii* is not only the earliest, but also the most easily grown of all, and unique in its habit. Its leaves are mottled in dark green and dark mahogany-brown. The two to six flowers are each borne on a separate slender scape

and form a sessile umbel. The general effect of a well-grown plant is of a loose bouquet with the two richly mottled leaves as a holder. The segments recurve to the stalk and are light yellow with an orange centre. Well-grown flowers measure two to two and a half inches across. The bulbs of *E. Hartwegii* are short and solid, produce small offsets, and do not dry out as readily as those of other species. Unlike most sorts they retain their vitality until late in the season, and are in good condition in February, when bulbs planted earlier are in flower. More care is required to grow most kinds of *Erythroniums* than the ordinary grower will give, but this species is a flower for every one.

### Fertilizers for Forced Roses.

AT the last meeting of the Dutchess County Horticultural Society letters were read from experts in various branches of horticulture in reply to questions sent out by the Secretary, and what follows is the answer given by Mr. John N. May to the question, "What is the best formula for a fertilizer for Roses under glass?"

"I understand this to apply to Roses forced for winter flowers, and no one answer can be framed so as to be adapted to all conditions of soil. I must presume that the soil used for growing Roses contains naturally those ingredients which are essential to plant-life, such as fairly good loamy sod does, and this can be obtained in almost every section. If it is very heavy, a little sand will make it porous, and if very light, a little clay should be added. For a soil like this the only addition needed is a fair proportion of well-decomposed manure, and, of course, manure from well-fed stock is the best. If one part of such manure, thoroughly rotted, is added to and thoroughly mixed with five or six parts of decomposed sod, the only fertilizer needed for Roses grown in it is a mulch not more than half an inch thick of well-decomposed manure. This should be put on in the fall, and a similar coat given every eight or nine weeks till the end of the season. When the days begin to lengthen at about the middle of January, and the plants are growing vigorously, they may have a watering of weak liquid-manure made from the droppings of different animals, used alternately, and applied every two weeks, and nothing more in the way of feeding the plants will be needed. Of course, there will be cases where the soil is deficient in some element of plant-food, such as potash or phosphoric acid, and this can only be determined by study and experiment by every grower for himself. The first care should be to find out what is lacking, and the next to supply it in proper proportions. This must be left to the judgment of every man, and although such matters may appear of small consequence, it is these small things which insure the highest success, and it is their neglect which makes the business of the florist and gardener an uncertain quantity. In a general way I may add that I believe more Roses and other plants have been killed and crippled for life by the use of stimulants than by any other one thing. The best of all fertilizers will be injurious if it is applied injudiciously, and the formula that will bring the surest success is plenty of fresh air, cleanliness, plain, wholesome food and practical common sense."

Fishkill-on-Hudson, N. Y.

W. G. G.

**Iris Japonica.**—This beautiful Iris, which has been in cultivation for nearly a century, ought to be in every collection of cool-greenhouse plants. It belongs to the rhizomatous section of the genus, and is perhaps better known as *I. fimbriata*. The bright green sword-shaped leaves are from one foot to eighteen inches in length, gradually tapering to a point, and are arranged in fan-like tufts, making an elegant plant even when not in bloom. The pale lilac or bluish flowers are three inches in diameter and beautifully fringed. The reflexed falls are a rich orange-yellow at the throat. The individual flowers are fugitive, but they succeed each other until each spathe has produced three or four. The plant blooms better when allowed to become pot-bound. My experience has been that it is best not to attempt to divide the roots until this is absolutely necessary, as the plant will not blossom till the second season after division.

**Thunbergia laurifolia.**—This lovely warm greenhouse climber, perhaps better known as *Thunbergia Harrisii*, is a most beautiful object when in full bloom. The plant is a strong and rapid grower, with opposite simple leaves, ovate-acuminate in outline, seven inches long by three wide, on short petioles. The beautiful lilac-colored flowers are three inches in diameter, and are borne in axillary and terminal clusters in the greatest profusion, but owing to the extreme delicacy of the petals a shaded position should be chosen for the vine if pos-

sible, as bright sunlight soon causes the flowers to fade. Its season of flowering is from the middle of January to the middle of March.

### Horticulture in Colleges.

To the Editor of GARDEN AND FOREST:

Sir,—Although not engaged in imparting horticultural instruction in the class-room, my experience having been rather in the line of receiving such instruction, yet I would like to emphasize some of the points brought out by Professors Munson and Waugh on this subject in your journal.

I am aware that in many of the land-grant colleges there is an urgent demand on the part of the farmers for the practical in teachings of horticulture. This is also true of experiment-station work. The situation is in no wise improved when we admit that this demand is made without comprehending those principles which underlie true education. We are bound to help those very people from whom the demand has come, so that for the present, at least, we must include in the college curriculum a certain number of the practical courses, but it would, indeed, be a feeble institution where instruction is given only in that portion of horticulture which could be learned quite as well from any gardener.

I agree with your correspondents that horticulture, in a certain sense, is an advanced study, and perhaps it should not begin earlier than the junior year, provided that the student has already taken such studies as chemistry, systematic, structural and physiological botany and the physics of soils; but if these subjects are to be taught wholly or in part as incidental to the courses in horticulture, two years is too short a period. Botany is one of the most important subjects as a foundation for horticultural study. The botany of cultivated plants receives too little attention in most colleges; it is considered a subject partly or entirely outside the domain of a systematic botanist, so that while the student may acquire a thorough knowledge of the wild plants of his vicinity, he may be able to tell you very little regarding the botany of the cultivated ones. I well remember when my professor in botany in college told me that I would not be able to determine a rose which I had brought from a neighboring garden, because it was a "cultivated form, and not a natural species." He was silent in regard to the origin or possible derivation of any of the "cultivated forms," and I was left to grope my way in darkness, or drop the matter as being wholly outside of science. I have since learned that all cultivated plants are to be referred to some natural genus, and that many forms which have been evolved in the garden are just as much distinct species, so far as any botanical characteristics are concerned, as those forms that we may gather from the forest or hillside, meadow or plain.

Plant propagation is a good subject with which to begin instruction in horticulture. A few lectures may be given with suitable illustrations, and the student can get the rest from Bailey's *Nursery Book* used in connection with laboratory work. I should be inclined to make the compulsory course a short one, however, and put most of the laboratory and manual work on the elective list. The improvement of cultivated plants is of great importance, and in this course may be taught the philosophy, principles, theories and laws relating to the subject. It seems to me that it is in a course of this kind, given in lectures or with the use of text-books properly elaborated by lectures, that the student receives his greatest inspiration and enthusiasm in the cultivation of plants.

Why not give short courses of a few lectures each on plant propagation, pomology, vegetable-gardening, floriculture and greenhouse construction and management, in which are taught the more important principles of the art, and leaving those phases of these subjects which are usually placed in the foreground, such as cultural methods and varieties, to be made the subjects of minor elective courses? Both cultural methods and varieties are constantly changing, and at the same time may be entirely different in different parts of the country. If a student intends to make horticulture his profession he should have instruction in all branches pertaining to it, and all he can get of each, but if horticulture is only added to fill out a more or less general course of training for the purposes of education, it seems far more important to "consider the principles on which the art is founded." It is of far greater moment that a man should be educated than that he be made a fruit grower or a florist.

I wish that landscape-gardening might be placed on the prescribed list. When traveling about the state and observing

how many country houses look bald and barren, how many others seem smothered behind a meaningless and confused mass of trees and shrubs, and how few home grounds are planted or cared for with any taste, one cannot help feeling how much more beautiful and cheerful rural and village homes would be if every owner had some elementary schooling in the principles of garden art. There is some excuse for requiring landscape-gardening in a general college course; a larger proportion will be influenced by it than by almost any other subject. For instance, the number of people who own homes is far in excess of those who grow fruit or vegetables for market, and why should we not know how to beautify the home as well as how to grow perfect Bartlett pears or Hubbard squashes? Every home which is made a model in the way of arrangement and planting remains for years a living example for thousands of eyes to feast upon, while the pears and squashes pass with the season. I would teach landscape-gardening as a fine art, and quite as worthy of patronage as music or painting. If every civil engineer and architect could receive good fundamental training in landscape-art what a world of natural beauty might then be preserved that is now ruthlessly destroyed!

I will only add that, whatever the curriculum, personal investigation by students should be insisted on, and that in every subject the more important literature should be mentioned and discussed.

Experiment Station, New Haven, Conn.

W. E. Britton.

### The Orange Fruit Worm.

To the Editor of GARDEN AND FOREST:

Sir,—This insect, alluded to on p. 91, was described and figured as long ago as August, 1888, in the first volume of *Insect Life*, page 45. It is there called the Morelos Orange Fruit Worm, *Trypeta ludens*. The orange growers of California are much exercised over this insect just now, and they are trying to induce Congress to pass an act establishing a national quarantine. I consider the danger a present one and see no reason why the pest cannot establish itself in our own Orange-growing districts. The maggot will probably flourish wherever the orange can grow, and while under natural conditions it would probably not reach the United States for many years to come, if at all, a dozen infested oranges exposed for sale for sufficient time in southern California might produce flies enough to stock the Orange groves of that region in a very few years.

Rutgers College, N. J.

J. B. Smith.

To the Editor of GARDEN AND FOREST:

Sir,—I am glad to note your remarks on the Orange-worm in your editorial of March 10th. On the Pacific slope of Mexico, the district about Yautepec and Cuautla, in the state of Morelos, is very badly infested. The chances are against finding a sound orange coming from that district, and in the City of Mexico one has to be on his guard against wormy fruit. The prevalence of the pest is, doubtless, largely due to negligence on the part of the orange growers. It is said that the Cordova district, on the Gulf slope, is also infested. I have, however, eaten many excellent oranges from that district, and fruit growers there are said to be more careful in their methods than in the Morelos valley. Two districts which are not infested are that near Lake Chapala, on the line of the Guadalajara division of the Mexican Central Railway, and the Hermosillo district in the state of Sonora, both of which now send large quantities of superb oranges to this country by rail. I am told that the Rio Verde oranges, near the line of the Mexican Central's Tampico division, are also sound.

It would be a calamity to have this pest introduced into the United States. Since the failure of the Florida crop, orange buyers from this country have been buying up all the available crops in Mexico. There is particular danger that, in the scarcity of oranges in Florida, fruit from these districts may be taken there as well as to New Orleans, Galveston and other Gulf ports, where the worms might at once find a favorable field. In the Morelos valley the Mangos are also badly infested by a similar worm, possibly the same species. If introduced to this country, the orange-worm might, perhaps, take a liking to other fruit as well.

It would be unfair to impose a prohibitory tariff on oranges from Mexico as a whole, for the Hermosillo and Lake Chapala districts supply the western sections of this country with fruit at seasons when they do not come into competition with the California oranges, and the Hermosillo crop, at least, is available long before the Florida oranges are fit to eat. But it is the imperative duty of our Government to ascertain all the

infested districts in Mexico and strictly forbid the importation of fruit from those parts.

The Mexican Government should also take rigorous measures against the pest and thus avert serious danger to an important and growing industry in that country. It has been suggested that, if all the wormy fruit that is now left to decay on the ground in the orchards were promptly destroyed, it would certainly reduce the damage from the pest very materially.

Malden, Mass.

Sylvester Baxter.

### Meetings of Societies.

#### National Fruit Growers' Convention.

THE continued spread of the San José scale, the recent introduction of several injurious insects from foreign countries, and the imminent danger of introducing the "Orange fruit worm" from Mexico into the Orange districts of the United States have thoroughly aroused horticulturists and fruit growers generally to the importance of protection against injurious insects. In almost every state, from New York southward and west to the Mississippi or beyond, bills have been introduced or enacted to regulate the distribution of nursery stock so far as it is possible to do so without coming into contact with legal interstate commerce. At almost every meeting of fruit growers, at almost every horticultural society and at almost every meeting of experiment station workers the question of destroying the San José scale or preventing its spread into new localities has been up for discussion. The matter was deemed so important that the Ohio Horticultural Society, at a meeting during the winter, issued a call for a delegate convention to be held at Washington, Friday, March 5th, to consider the possibility or advisability of securing legislation by the National Government in the direction of enforcing a quarantine against the introduction of foreign insects and the regulation of the transportation of nursery stock between the states.

In response to this call a large number of delegates met at Washington, Friday, March 5th. Most of the central states, many of the northern central states, most of the southern states, middle Atlantic states and California were represented at the convention. In some cases a number of delegates attended from a single state representing different societies, and a considerable number of entomologists and horticulturists from the experiment stations were also present. There were a number of attendants who did not figure as delegates, but to whom the privileges of the floor were extended, and altogether there were at times nearly a hundred persons in the room in which the meetings were held. During the morning session several papers were read in which the possibility of regulating or preventing the spread of insects and fungous diseases by law was considered, and in a paper by B. M. Lelong, of California, that state's experience was detailed. Dr. L. O. Howard and Mr. B. T. Galloway, of the United States Department of Agriculture, read papers on insects and fungous diseases, respectively, and made suggestions as to the lines in which legislation was possible. The outcome was the appointment of a legislative committee of ten, in which nurserymen, fruit growers and experiment station workers were represented, to whom was intrusted the duty of preparing an outline of such legislation as was considered advisable. This committee organized immediately, electing Mr. William B. Alwood, of the Virginia Station, as its chairman, and a hearing was had during the afternoon, at which all the members present had an opportunity of giving their views on the subject of what such legislation should consist of. Quite a number of bills had been prepared in advance, embodying the opinions of the writers, and several of these were read to introduce and excite discussion. The sessions were continued until late in the evening and resumed on the morning of the 6th, when the committee finally reported that they had been unable to agree upon any proposed legislation for individual states, but suggested that all acts should contain a provision for the periodical examination of nurseries and fruit farms, and should provide also for power to compel the destruction of dangerously infested stock of all kinds. It was deemed best to deal with the subject of interstate commerce and national quarantine in one bill, and the following was finally agreed upon by all the interests, after it had been discussed section by section.

The importance of this meeting cannot be overestimated. It is the first time that any large body representing not only experiment-station workers, but nurserymen and fruit growers, had met to discuss the subject, and at first it seemed that interests were so diverse that no agreement could be reached.

It was realized, however, during the discussions that reasonable protection only was contemplated by the persons interested, and that, after all, the objects sought to be obtained were for the ultimate benefit of all concerned. Nurserymen and fruit growers were interested on the same side, and finally every section of the bill was adopted without a dissenting vote. The legislative committee was continued, with power to appoint an executive committee, and the officers of the convention, Mr. Cushman, of Ohio, being elected president, were given power to call further meetings in case it proved necessary or desirable.

The title of the proposed bill states that it is an act to provide for inspecting and treating plants, buds, cuttings, nursery stock and fruit imported into the United States or grown within the United States and becoming a subject of interstate commerce. Section 1 authorizes the Secretary of Agriculture, at the expense of the owner of such imported stock, to retain it in quarantine at designated ports, where inspectors appointed by him may examine it to ascertain whether it is affected by any dangerously injurious insect or disease, and provide for its treatment when necessary. Section 2 provides that when such plants, etc., are found infested they shall be treated at the expense of the owner or shall be destroyed when their condition warrants destruction; but an appeal from the inspector's decision may be made to the Secretary of Agriculture within three days after the inspection, and the Secretary's decision shall be final. Section 3 provides that if imported plants, fruit, etc., are apparently free from dangerous infection a certificate to this effect shall be issued to the owners by the inspector, and this certificate shall release the plants from further restriction, either at the port of entry or in interstate commerce. Punishment by fine and imprisonment is provided against counterfeiting, altering or defacing such certificates. Section 4 provides that when the Secretary of Agriculture is convinced that proper inspection and treatment for exported plants are furnished in any foreign country, he may by proclamation accept such inspection and treatment in the place of that performed by his own officers. Section 5 provides for the proper inspection and treatment at the expense of their owners, and before their shipment, of all plants, buds, scions, etc., which are subjects of interstate commerce, and are about to be transported from one state into another. Section 6 provides that this examination shall be made under rules prescribed by the Secretary of Agriculture, and that plants found free from danger and properly certificated may be released from further quarantine and restriction in interstate commerce, and it provides for the punishment of persons who counterfeit or destroy these certificates. Section 7 makes it a misdemeanor to transport from state to state any plants, buds, cuttings, etc., which have not been examined in accordance with Sections 5 and 6, or which have been declared by inspectors to be dangerously affected. Section 8 authorizes the Secretary of Agriculture to accept an inspection by any state, territory, corporation, firm or person which he may consider proper and competent, in lieu of inspection by his own officers.

### Recent Publications.

*Vegetable-growing in the South for Northern Markets.* By P. H. Rolfs, M. Sc., Professor of Horticulture in the Florida State Agricultural College. Richmond: Southern Planter Publishing Co. 1896.

This manual consists of what were originally lectures delivered to classes in horticulture, but in process of revision they have lost their fragmentary character and the book has assumed the form of a systematic treatise. The reader must understand that earliness in the production of vegetable crops for northern markets is a matter of prime importance, so that the directions for cultivation, fertilizing and the like are given largely with this end in view. Nevertheless, the concise discussions on soils, their composition and character, the reasons for their exhaustion and the methods of restoring and enriching them, are useful to any one who has a vegetable garden or truck farm. In the list of vegetables described northern readers will be interested in such kinds as collards, for example, which the people of the south prefer to either cabbage or cauliflower; in goobers, which look like large one-seeded peanuts; in yams, which have never made serious inroads on the popularity of either the Irish or the sweet potato, although it was thought at one time that the Chinese and the Cuban

yam might replace them. By way of exemplifying the difference in garden practice at the north and the south a brief account of the southern method of cultivating Celery may be interesting. The seed is sown in July or August and in a cold frame, although, of course, this is not for protection against low temperature, but so that the young plants can be shaded from the hot sun. Very rich soil is used and plants are set out in October or November when the seedlings have leaf-stalks about three inches long. The great bulk of the cultivation is done in the seed-bed, and the plants are only hoed once or twice after the setting out, and then the earth is drawn up to the rows in an A-shaped ridge for bleaching, although this is sometimes done by banking with boards. The crop is ripe at the season when visitors are abundant in the south, so that very little of it comes to the northern seaboard markets, which are supplied largely from Kalamazoo, Michigan, and other northern points where the celery is kept stored for winter use. Spinach is sown in September or October. The seed of Kale is sown in October or November in cold frames, like Celery, and it is sent to northern cities during March, April, or even earlier. Peas are planted the last of October or in November, and so on.

The methods of transplanting, watering, fertilizing and cultivating are given with great detail for all the various kinds, and there are specific directions about making crates, packing, marketing, shipping, raising seed and preserving it for home use. The book contains 250 pages and it is written in a clear style, with as little use of technical language as possible, so that any one of ordinary intelligence can understand it. Altogether, it can be thoroughly recommended to any one interested in the growing of truck and vegetables in our southern states, and we may add that northern growers will find it singularly suggestive from the very fact that the methods of culture recommended are so strikingly different from those needed here for the same class of plants. If, for example, a certain crop is known to thrive here under one treatment, and in Florida under quite another, it will be comparatively easy for an observing student to judge what conditions are the essential ones needed by the plant and what points are of minor importance.

### Notes.

Some of the lumber-trade journals are writing in favor of soft elm for the interior finish of buildings and assert that wherever it has been used in the western cities it has proved very satisfactory. It has long been used in the manufacture of furniture, where it has taken the place of plain oak, which it much resembles in grain, and there seems to be no reason why it cannot be used to good advantage in this new field.

In some of the fancy-fruit stores are seen considerable quantities of Sapodilla plums, the fruit of *Sapota Achras*. These so-called plums are as large as an ordinary apple and have a rough dull russet skin. Those now offered in this city were evidently picked when very unripe and are yet hard and uneatable. The fruit is only fit for use when it begins to decay, as it then loses its acrid milk. The skin becomes marked with black blotches and the flesh is a dull yellowish tint, soft and exceedingly sweet.

In a bulletin on the timber lands of Minnesota, prepared by Professor Green and Mr. H. B. Ayres, after it is shown that as the lumber business is now carried on in that state, the forest as a resource is constantly diminishing, it is estimated that the normal yield of the present forest area in its best condition and protected from fire would be about 2,000,000,000 feet, board measure, every year. That is, this supply, which could be maintained indefinitely, and perhaps even increased, is nearly twice as much as is now cut in the state.

A correspondent of *The Garden*, writing from the north-western coast of Spain in the middle of February, speaks of *Magnolia conspicua* in full flower, and *Camellias* as past their best. Chinese *Azaleas*, *Acacias* of various forms, especially *A. dealbata*, *Spiræas*, Flowering Currants, *Ribes sanguineum*, were in full bloom in the gardens, while the hedges and banks were blue with flowers of *Lithospermum prostratum*. Primroses were open along the banks of streams, and in shel-

tered hollows Dog-tooth Violets and Narcissus Bulbocodium were growing beneath the Pines, and among the Chestnuts the white Squills, yellow Oxalis, blue Myosotis and many other flowers were in full bloom.

The early settlers in the distant west found such a wonderful forest growth that their first thought was to cut it out of the way to make room for farms and vineyards. It is encouraging to observe that they now begin to realize the necessity of husbanding this most valuable of their natural resources. We note with pleasure that there is now before the Senate of the state of Washington an act to create a Board of Forest Commissioners, who are to collect and disseminate information concerning the trees native to the state, to study other forestry problems, to enforce the laws for protecting timber against fire and trespass, and to employ forest wardens, who shall patrol the woods in the dry season and assist in the prevention and suppression of forest fires. Another specific forest-fire bill has been introduced in the same body, and this makes the willful or careless kindling of a fire in the forest a misdemeanor, compels railroad companies to use spark-arresters on their locomotives and to use due caution about leaving hot coals where they may be dangerous.

Iris Bakeriana, which was discovered in Armenia in 1889 and disseminated by Herr Max Leichtlin, has become very popular in English gardens, and a late number of *The Gardeners' Magazine* gives a portrait of some of the flowers selected from plants which had just taken a first-class certificate at the meeting of the Royal Horticultural Society. In this country we do not avail ourselves as we should of the beauty and variety of the early Irises like those of the Reticulata class and a few others which come with the Snowdrops. Three years ago Mr. Gerard wrote of Iris Bakeriana that it had never disappointed him and was increasing at a fair rate, and on another page of this issue he gives it the highest praise. The flower is quaintly beautiful in form, and although individuals vary in color its prevailing tints of deep purple, or indigo-blue, light blue, and white spotted with violet are always harmonious and pleasing, and more than this it has a distinct fragrance. Even if these flowers were less beautiful their appearance in our wild spring weather, when they have so few rivals, would be a delight.

The Agricultural Appropriation Bill did not receive President Cleveland's signature, and therefore the iniquitous seed grab will once more come before Congress, and the country will have an opportunity to find out what sort of a man the new Secretary of Agriculture is. Mr. Morton's honest efforts at reform were defeated by the ignorance and folly of Congress. Now the question is open again, and the Seed Trade Committee has issued a circular for the purpose of enlightening public sentiment and arousing the moral activity of the people against the senseless and wicked free distribution of seeds by the Government. No doubt, a great portion of the twenty million packets of seed which are given away are wasted, but still it is a blow at the business of every honest dealer in seeds. There would be reason in an intelligent distribution of improved varieties of plants and of novelties properly placed among the experiment stations for testing, but this burdening of the mails with tons of seeds is not only a shameful extravagance, but it degrades every recipient to the rank of a pauper and obstructs honest business at a time when success is difficult even with the greatest economy and skill.

For some years past, potatoes in many parts of the country have shown unsightly pimples or projections on their surface, which have seriously diminished their value. The cause of this pimply condition has not been thoroughly understood until certain investigations carried on by the New York Experiment Station in Long Island showed that the injury was worked by a small flea-like beetle, well known as the black cucumber beetle, which has been detected in eating holes into the leaves of the Potato and Tomato just as it does in the leaves of the Cucumber. These voracious insects, however, are not the immediate cause of the mischief, but minute white grubs which are hatched from the eggs laid by the female beetle. These grubs burrow into the tuber and cause the pimples and the sliver-like projections which accompany them. The pimples result, it is probable, from the irritation caused by the worm, and the slivers are slender canals in which a single grub feeds. Either one of these characteristics of the disease may be found without the other. Bulletin 113 from the Geneva Station gives this important information, and states clearly how the disease can be controlled. The Bor-

deaux mixture, which has been found useful for so many purposes, is an efficient remedy here also, and when thoroughly and intelligently applied it keeps the beetles away from the plants.

Many of the vegetables coming from the south now are injured by heating during transportation, and others are inferior because they are the last of the crop. Eggplants are comparatively scarce, and sell for twenty to thirty cents each; string-beans command twenty-five to thirty cents a quart, and peas \$1.00 a half-peck. New Florida cabbage brings ten to fifteen cents a head, and turnips and beets, from Florida and South Carolina, cost seven and ten cents a bunch. New carrots come from South Carolina, Florida and the Bermudas. Spring onions, from New Orleans, cost seven cents a bunch. An increasing demand for tomatoes has made somewhat higher prices for this vegetable, the Florida product selling for twenty-five cents a pound, and that from northern hot-houses at thirty-five to fifty cents. Kohl-rabi, radishes, French artichokes and cauliflower are among the fresh vegetables now in season. The latter is from California and near-by hot-houses, and small heads cost thirty to fifty cents apiece. Good asparagus is coming from South Carolina in large quantities, and sells for sixty cents to \$1.00 a bunch. Bermuda and Cuba potatoes cost fifty to sixty cents a half-peck, and sweet potatoes, from New Jersey, twenty-five cents a half-peck. Lettuce, from Florida and from Boston, brings ten to fifteen cents a head, and hot-house grown cucumbers, also from Boston, fifteen to twenty-five cents each. Mushrooms cost sixty cents a pound.

Mr. W. Botting Hemsley writes entertainingly in a recent number of *Knowledge* about Captain William Dampier and his voyage of discovery to western Australia about two centuries ago. Fortunately, Dampier was a keen observer and knew something of botany, so that his descriptions of the flora, as well as the specimens he brought home, were exceedingly useful. In his book he describes a "sort of creeping vine that runs along on the ground, having a blossom like a bean blossom, but much larger, and of a deep red color, looking very beautiful." This was the first account of what came to be known as *Clianthus Dampieri*, the brilliant Glory Pea, one of the few plants figured in Dampier's work, *A Voyage to New Holland in 1699*. This is one of the most gorgeously beautiful plants of the great Pea family, and although it has been in cultivation in England for years it requires a skillful gardener to bring it to perfection. The flowers are four or five inches long, of a rich crimson red, with a flashing purple-black centre and a velvet-like texture. Another species of the genus, *C. puniceus*, was discovered in New Zealand by Sir Joseph Banks during Captain Cook's first voyage, and it proves much more easily cultivated than the Australian species. Since the Glory Pea grows with such luxuriance in its home it would seem that it ought to be within the skill of the gardener to cultivate it with more pronounced success.

Mr. Robert Thompson, of Bogota, in the Bulletin of the Botanical Department, recommends the naturalization in Jamaica of *Odontoglossum crispum*, which is found on the western slopes of the Colombian Andes, between the third and fifth parallels of north latitude, since the temperature of the Cinchona plantation, which is situated between 4,000 and 6,000 feet of elevation on the Blue Mountains, coincides with that of the natural habitat of *O. crispum*, and the wet seasons and dry seasons of the two places are very nearly similar. In the centre of the area of the natural distribution of these Orchids is the so-called Pacho District, from which most of the fine types come. Here the flowers are remarkable for varietal diversity, ranging in color from white to rosy mauve, and differing in size, form, substance, the spotting of the segments, and in almost every other particular. Their arching racemes remain in bloom about two months, and they flower almost the entire year through. Seeds are produced in great abundance, and, being extremely minute and light, they float in the air and are widely disseminated. Mr. Thompson thinks that if healthy plants were tied to the branches and trunks of the Cinchona-trees in Jamaica, or in separate groups in the forests of the Blue Mountains, most of them would flower in a year and seeds would mature in a few months. Within a couple of years they would be dispersed all over the forest, and in ten years plants fit for export could be had by the thousand. In order to show that this project is not visionary, it is stated that the Nun Orchid, *Phajus grandifolius*, which was introduced into the Botanic Garden at Jamaica many years ago, is now abundant on the highlands of the interior.

## Roadside Trees.

WE have often spoken of the beauty of our country highways and byways, especially in hilly and rugged sections, when nature is allowed to furnish beauty and shade in her own way with shrubbery and trees by the roadside. Every one can recall some example of a particular stretch of road which has come to be a personal delight, and then has been made desolate by the wanton work of some pathmaster or property-owner whose land abutted on the highway. In most states it is the privilege of landowners to do what they will with the plants by the roadside in front of their fields, and noble trees have too often in this way been sacrificed to the greed of private owners. Where a venerable tree stands by the wayside it becomes a part of the scenery, and as it has from time immemorial given pleasure to the entire community, every one who passes it feels that he has in some sense a right of property in it. We can recall one instance where three White Oaks had stood for nearly two centuries on a roadside in northern New Jersey. Men well advanced in life had heard their grandfathers speak of them as large trees when they were boys, and in the course of their long existence they had never harmed any one, but had been a source of delight to thousands. One day the owner of the property abutting the road was offered a few dollars for each of the trees by the operator of a sawmill, and in a few hours the trunks of these venerable landmarks were made into sawlogs, and the landscape lost an ornament which could not be replaced in a hundred years.

In most cities the owners of building lots are not permitted to do as they will with the street trees. These cannot be removed without a permit from some municipal authority, and why should not this rule be extended to the country? Certainly, trees are as beautiful and useful along a rural road as in a city street. Indeed, if the landowners in a farm region knew that the beauty of any countryside was a real factor in its money value they would be more careful how they defaced or mutilated the scenery by felling trees and disturbing wayside shrubbery. Many country places receive the largest part of their annual income from sojourners in the summer who leave the city for a

season of rest, and the general appearance of the country very often determines the tide of travel. It is, therefore, destructive of their own interests when the inhabitants of any section use the axe to obliterate natural beauty and rob their roads of all shady attractiveness.

Massachusetts began some years ago to enact laws for the protection of wayside trees, and Mr. Christopher Clarke, Trustee of Public Reservations, writes to the *Springfield Republican* to protest against cutting down these adornments of roadways. He asserts that if the destruction continues at the present rate it will not be long before every beautiful wooded drive or shaded road will be stripped bare and have nothing left but a hot and barren road, so that the principal attraction of many Massachusetts towns for former residents or summer visitors will be lost forever. He quotes one law in particular which gives the selectmen of a town, as well as certain city officials, an opportunity to mark roadside trees to be saved whenever a wood lot is to be cut, or when for any cause a tree is in danger, and such designation makes the preservation of this tree permanent. When such a tree is selected for preservation a spike is driven into it with the letter "M" at its head, and these spikes are furnished free by the Secretary of the State Board of Agriculture. Among the provisions of the various laws quoted are these: (1) No person shall cut down or injure any tree on any street or public road in the state; (2) no such tree can be legally cut down by any one except after due notice has been given or made to the selectmen of the town or the municipal authorities and proper consent given; (3) the penalty for cutting down a roadside tree is a fine of not less than \$5.00, or more than a hundred, one-half of which goes to the complainant, and the other to the use of the person upon whose property the trespass was committed; (4) a like fine is enforced if a marked tree or any other tree outside the fence or the line of the wood lot or homestead is cut down without authority, one-half going to the complainant and one-half to the city or town; (5) these laws apply to trees before any citizen's residence, farm or wood lot, bordering on any public road or street, and no roadmaster, forester or highway surveyor can cut down a tree without leave specifically granted by the city or town after a proper hearing.

We do not know how many other states have laws of this character, but certainly there ought to be enactments of this nature in every commonwealth. It is not generally known, even in Massachusetts, that some of these laws now exist, and Mr. Clarke asks every editor in that state to copy his letter, so that the people can take advantage of a protection that has been secured for them in the shape of legislation which will, if properly enforced, stop the wholesale destruction of beautiful trees still standing. It is especially urged that city and village improvement societies and rural clubs throughout the state unite in enforcing these laws, and we have no doubt that the conviction of a few offenders will do much to save trees in the future. Another suggestion made by Mr. Clarke is an admirable one: where large and beautiful trees are standing just outside of the line of streets or roads and on private grounds the trees might be purchased and allowed to remain and be marked for protection, so that at a nominal cost a continuous and effective shade could often be secured.

Certainly it has been too long the prevalent opinion that a tree has no value. Telegraph linemen, trolley-road layers and their employers generally have thought nothing of chopping down any tree which chanced to stand in the way of their work. These offenders have sometimes been brought to justice in courts of law, but they too often escape when the trial comes before a jury because these men cannot be convinced that the cutting of a tree inflicts any damage that a grown man can feel. Organization will do much to save the refreshing beauty of our country roadsides. This has already found expression in Massachusetts law, and if the same organization will strive to enforce the law the conviction of a few vandals will inspire

the rest of their class with some wholesome respect for public sentiment if they take no delight in rural beauty.

### Sculpture in Gardens.

IF those restless spirits that possessed the Gadarene swine were to enter into the statues of Edinburgh, and if the whole stony and brazen troop were to hurry and hustle and huddle headlong down the steepest place near the city and into the deepest part of the Firth of Forth, art would sustain no serious loss." This is the picturesque language of Lord Rosebery in a recent speech, and it is quoted by Mr. William Robinson in his paper, *The Garden*, in an article in which he briskly attacks the use of sculpture in gardens. He goes on to say that the *Pall Mall Gazette*, in commenting on Lord Rosebery's words, expressed the wish that the "London monstrosities" would unite for the same sort of rush into the Thames. Mr. Robinson's comment is that when politicians and journalists begin to ask for deliverance from the statuary with which city squares and streets are adorned the lovers of nature are not likely to be infatuated with this kind of adornment for gardens, although there seems to be a renewed effort by some writers on garden art to make more of stone and less of verdure. It is often observed that good statues are more rare than good examples of painting or of the other fine arts, and this is one reason why the use of statuary in gardens is rarely effective, because a bad statue, however well it may be placed, can never be pleasing. Sculptors of distinction, as Mr. Robinson reminds us, do not usually concern themselves with garden designs, and when the architects or landscape-gardeners attempt to imitate the human form the work is foredoomed to failure. Probably no one who realizes the proper use of natural beauty in a garden would think of it as a place for exhibiting bad art in stone or cement. Every one has seen beautiful old walls in English gardens, and there is a kind of beauty in the architectural features of the old Italian gardens, although many people suspect that it is the beauty of decay; that the broken columns and crumbling statues are more impressive now than they were in their prime, from the very fact that their dilapidation tells their age and invests them with a halo of romance. However, we will let Mr. Robinson speak for himself, and quote the main part of his article:

Many foreign gardens are bestrown with statues and sculpture, though in northern countries like ours a statue of real value as a work of art deserves to be protected by a building of some kind, and the scattering about of numerous statues of third order of artistic value, or of no merit at all, which we see in some Italian gardens, often gives a very ugly effect. If a place is used for the exhibition of sculpture, well and good. But let us not in that case call it a garden, as it ceases to be one in the true sense. The great costs of such works should preclude their use, if there is no other reason, and getting the many beautiful living things which our gardens may be a home for, is the best use for the money we spend on them. The dotting of statues about the public and private gardens of Paris and London is destructive of repose, exactly in the degree to which it is carried. In Britain, statues are often of cast material, and what their effect is all who have seen them know. The people who use gardens to be spotted about with works of art do not understand that the garden is the best of all places to show the work of nature, and the most beautiful of natural forms is what one should expect to see here. The earliest recollection I have of any large garden or country-seat is of one strown with the remains of statues, and to explain its effect I quote from one of the novels of Monsieur Victor Cherbuliez: "He passed before the open gate of a spacious garden which formerly presented to the admiration of visitors beautifully straight alleys bordered with nicely trimmed globe and cone-shaped Yews, shrubs arranged in angles or in chess-board form or devised to imitate a wall, with sheared trees and statues everywhere. It was one of those classical gardens whose planners prided themselves upon being able to give nature lessons in good behavior, to teach her geometry and the fine art of irreproachable line. But nature abhors such lines. She is a reluctant pupil of geometers, and submits to their tyranny with an ill grace. The garden which Lionel entered had been badly kept after the death of the Baron, and

decay had degenerated into ruin. The large basin no longer held any water, and the dolphins which once spouted it from their throats seemed to be asking each other why they were in this world. But the statues had suffered most. Moss and a green damp had invaded them as if some plague or leprosy had covered them with sores, and pitiless time had mutilated and insulted them. One had lost an arm, another a leg, and almost all, their noses. There was a Neptune with a damaged face and nothing left but his beard and half his trident. Rain water stood in the hollow neck of a Jupiter without a head, and a little Pan, with his back against a rock in a thicket, stood where he had blown his pipes for near two centuries, but he had no longer any pipes or hands or breath."

Mr. Robinson adds to this a suggestion which certainly ought to be considered, namely, that while stone will wear away in any climate, it will crumble most rapidly in the cold north, where frosts and thaws and rain and drought occur in such severe succession. Stone-work, wherever it is unprotected in northern latitudes, rapidly disintegrates. The face of a marble statue will be seamed and scarred in a few years, and stone balustrades and terrace-work quickly decay.

### *Pinus palustris* in France.

SO far as I know, the two trees figured on page 115 are the only Long-leaved Pines of respectable size now existing in France. They stand at Geneste, some eight miles from Bordeaux, near the border of the sand hillocks which stretch to the sea and near the famous Médoc district. And yet the Long-leaved Pine once created considerable excitement in France, and large returns were anticipated from planting it. The journals and reviews of about 1830 contain many references to the tree, and François André Michaux read a lecture before the Royal Agricultural Society in praise of its timber. He considered the name *Palustris*, given to it by Miller, as inappropriate in view of the sandy soil where the forests of this Pine grew, and he added that, if we can judge from the language of Miller himself, there were more specimens of the tree growing in English gardens in the middle of the last century than there were in his own time. Michaux stated that trees near Philadelphia had endured a temperature of fifteen degrees, Réaumur, uninjured, which testified to its hardiness, and considering its ability to grow in the poorest soil, in connection with the beauty, strength and durability of the wood and its capacity to produce turpentine, it ought to become of economic importance in the south and west of France.

In the same year seeds were distributed by the Minister of Agriculture among all who were willing to experiment with them, and quite a quantity was sown in Fromont, the celebrated establishment of Soulange-Bodin, to furnish amateurs with the young plants. Soulange-Bodin made an extensive report in 1831 of his sowings, and referring to the prospects of the tree he says that "it ought to succeed in the Live Oak region," which was an accurate statement.

To return to Geneste. The estate was then owned by Monsieur Ivoy, a gentleman interested in agriculture and forestry, who planted in his park a good many American trees, especially Oaks and conifers. In 1831 he sowed some poor seed of Long-leaved Pine, and the twenty-three seedlings that resulted looked like tufts of grass without stems at the end of the year. Some of these were planted not far from the house, and thirteen years later they were all thrifty but one, the largest being twelve metres high. The only care given to the trees was some superficial hoeing, and last December one of the trees measured eighteen metres in height, and another sixteen metres, while the circumference of the first at one metre from the ground was 1.70 metres, and of the other was 1.50 metres.

Close to these Long-leaved Pines is planted a Loblolly Pine, and the volume of this tree is more than twice that of the Long-leaved Pine. We gather from the notes of Monsieur Ivoy that they were planted the same year. Another plantation of *Pinus palustris* was made in 1827 by Mrs. Aglaé Adanson in her park near Moulins. Three or four

trees were alive sixteen years later, and they had endured some severe winters; but this is a cold region, and they were killed before they attained any stately proportions. So did most of the trees at Geneste. The two survivors were further from the lake and on higher ground than their fellows. No Loblolly Pines at Geneste have been killed by frost, and a beautiful specimen is living on the small island in a brook hardly above the water-level. Fine specimens of Liquidambar, Bald Cypress, Cedrus, many Oaks, Hickories and Tulip-trees add to the interest of the place, still possessed by the granddaughter of Monsieur Ivoy.

Michaux, as we have said, rather overrated the importance of the Long-leaved Pine for planting in France, and his confidence that it could be grown under the same conditions as the Pinaster and furnish superior and more abundant products in the shape of timber and turpentine was not justified. The Pinaster, or Maritime Pine, as it is commonly called here, can be safely planted in the south-west and west of France, where thousands of acres are planted with pure forests of this tree, although there may occur two or three winters in the century which will freeze the tree in central France. The seed of the Pinaster is abundant, cheap, and can be sown like grass on the heath, and the young seedlings will make long shoots from the first and quickly overtop other growth. The Pinaster also gives prompt returns of wood and turpentine, and trees twelve years old can be cut down to make posts for wine galleries and will give rosin before they are twenty years old, if planted far enough apart from each other. At thirty years it furnishes a fair amount of timber of poor quality, and at forty the tree is old. Again, the Pinaster is an excellent tree to protect the coasts of the south-west against sand-drifts, which formerly advanced from the sea until they were successfully resisted by this tree. Compared with this tree the less hardy Long-leaved Pine will flourish in a more restricted area. It would require greater care and much longer time to grow into merchantable timber. According to Dr. Mohr,\* it ought to stand until it is from 90 to 140 years old. The trees at Geneste, although sixty years old, are still practically valueless, while the Pinaster would have paid twice the rent of the soil. Finally, where there is no habitual and fairly large production of any product, the disposition of it at a paying figure is always difficult. Small copses or woods, small forests and individual lots of trees seldom make a profitable speculation. If there were a chance of growing any American Pine in company with or in place of the Pinaster, the Loblolly would be better than the Long-leaved Pine, as it would, at thirty years, afford a greater quantity of timber superior to that of the Pinaster, and which might possibly find a market.

The timber of the Long-leaved Pine imported into this country has been largely used under the name of Pichepin, an evident corruption of Pitch Pine. Struck by the beauty of the wood, many planters in France have tried to grow the tree that produces such fine timber. They have sent to America for seeds of the Pitch Pine, but to the seedsmen of New York and Philadelphia this meant the seed of *Pinus rigida*, so that nine buyers out of ten have received what they did not want. This confusion arises from the similitude of the two words in different languages. In France, as in America, *Pinus rigida* will give no timber of the first quality and is good only for fuel. Its place is in the sandy soils in districts too cold for the Pinaster, where the rainfall is large or the water-table near the surface. In rich soils it will grow to form picturesque specimens for parks, but it is not of economical importance in this country.

Paris.

Maurice L. de Vilморin.

The Pitch Pine is the most cheerful of our trees in early spring. When seen on a distant hillside it harmonizes perfectly with the yellow sand and the March sunshine; indeed, it has an ingrained sunniness which gives the landscape just the warmth it needs.—*Thoreau*.

\* *The Southern Pine*. United States Department of Agriculture, Washington.

## Foreign Correspondence.

### London Letter.

ENGLISH ORCHARDS formed the subject of a lecture by Mr. George Gordon, editor of *The Gardeners' Magazine*, before the Society of Arts on March 3d. Mr. Gordon has for years preached the gospel of English fruit, and last year he sent a specialist to report on the condition of some of the orchards in various parts of England, the result of which he published. It revealed, on the whole, a deplorable state of things, as deplorable as the condition of, for instance, some departments of agriculture in this country. The farmer will not grow wheat nor potatoes at a loss, nor will the orchardist grow fruit which he cannot now sell at a profit owing to foreign competition. It has been shown again and again, by men who have tried, that such products as apples and pears are bad business in England unless one is specially favored. On the other hand, strange though it may appear, it pays to grow these fruits for one's own use; it is only when one goes into the market with his fruit that he finds himself undone by the foreign article. After all, the middleman must live. As to the quality of English-grown apples there can be no two opinions, ours being first, and the rest nowhere. Cox's, Blenheim and Ribston Pippins among the dessert kinds, and Bismarck, Prince Albert, Lord Suffield and Echlinville among cooking varieties, cannot be equaled by the best of imported fruits. Mr. Gordon says that the hundreds of inferior varieties now occupying our orchards should be burnt and replaced by such sorts as those here named, and that apples worth from £10 to £20 per ton are surely more profitable to grow than those which will not realize more than from £1 to £5 a ton. If orchardists saw any chance of obtaining these better prices, no doubt they would hasten to follow Mr. Gordon's advice. Englishmen, even when gardeners and farmers, are not, as a rule, asleep to their own interests. Mr. Gordon says we grow too many sorts. "Before we can make our orchards profitable we must follow the example of the American growers, and instead of planting two or three trees each of a hundred varieties we must plant a hundred trees each of a few varieties, and these of the very best."

*PICEA OMORICA*.—*The Gardeners' Chronicle* this week publishes a picture of a cone-bearing branch of this, the Servian Spruce, which is represented by a group of healthy young trees in the Kew Arboretum, raised from seeds obtained from Belgrade about ten years ago. It promises to be a good plant for England; at any rate, the Kew plants are exceptional, both as regards health and rate of growth, compared with other Spruces, last year's shoots being from a foot to eighteen inches long. The leaves are less than an inch long, almost flat, instead of being quadrangular, as in other Spruces, with two whitish lines on the upper side. The cones, which are one and a half inches long, are produced in clusters, sessile on the stronger branches, or terminal on the short lateral shoots. The tree is a native of the mountains of Servia, Bosnia and Montenegro. In stature it is said to equal any of the European Spruces. Its nearest ally appears to be *P. ajanensis*.—[*Picea Omorica* was raised in 1881 in the Arnold Arboretum from seeds sent by Dr. Bolle, of Berlin. It has grown rapidly in Massachusetts, where it is perfectly hardy and promises to be a distinct and useful ornamental tree.—Ed.]

*RHODODENDRON PRÆCOX* is one of the greatest treasures we possess as a shrub for beautifying the garden both inside and out in early spring. The mildness of February this year has specially favored it, and the scores of bushes of it in the shrubberies and beds outside have been glorious pictures of rosy mauve for the past fortnight. Nothing could be more beautiful, and I would class it with *Forsythia suspensa*, *Magnolia conspicua*, *M. stellata* and *Jasminum nudiflorum* as a first-rate early-flowering hardy shrub. It is, of course, as hardy as the Alpine Rose, but a snap of frost is apt to spoil its often too venturesome flowers. Indoors it is almost equally valuable, for it forces

well and the flowers last and keep their color. Its near ally, Rosy Bell, is almost as useful. These two plants are hybrids, for which we are indebted to Messrs. Davies, of Ormskirk, near Liverpool. R. Nobleum is also exceptionally good this year, the flowers being large and bright in color. It has been in flower out-of-doors since the middle of February.

**CYPRIPEDIUM FAIRREANUM.**—As bearing upon the subject of raising rare and valuable Orchids from seeds obtained artificially and without crossing, which I suggested in one of my letters as worthy consideration, the following is interesting: In the Journal of the Agricultural-Horticultural Society of India for December, 1896, p. 534, it is stated that Messrs. F. Sander & Co., St. Albans, will give £1,000 for an importation of *Cypripedium Fairreanum*, the habitat of which is unknown, but is suspected to be Burma. The same firm also offer £1,000 for a good plant in flower of *C. insigne*, with the flower pure white and of normal size. The albino is not likely to be forthcoming, although seeing how many albino sports among Orchids are now known, such a plant may possibly be found. The importation of *C. Fairreanum*, however, ought not to be difficult. It is estimated that a pod of *Cypripedium* contains about four million seeds; *Cypripedium* seeds vegetate freely and plants are quickly grown from them; a pod of ripe seeds of *C. Fairreanum* ought, therefore, on this showing, to be worth a considerable sum.

**BERTONERILA.**—This is a composite name for a bigeneric hybrid between *Bertolonia* and *Sonerila*. *Bertolonia* is a genus of some six species, all South American, while *Sonerila* is East Indian and comprises some fifty species. According to the *Genera Plantarum*, the two genera belong to different sections of Melastomaceæ. We owe the cross to Monsieur Linden, of *L'Horticulture Internationale*, Brussels, who publishes figures and descriptions of six varieties with popular names. The characters of the two parents are evident in the foliage of the hybrids, which are blotched and spotted with white and rose on a green ground. The names of the parents are not given, but I suspect they are *B. maculata* and *S. Hendersoni*, or near allies of these. For furnishing the surfaces of large pots in the Orchid-house or stove we find *Sonerilas* and *Bertolonias* most suitable, and, no doubt, these *Bertonerilas* will be equally serviceable.

**PITCAIRNIA CORALLINA.**—The *Pitcairnia*s are considered either weedy or too botanical by cultivators, but this species deserves to be ranked with handsome winter-flowering stove plants. It forms a tuft of erect lanceolate Curculigo-like leaves a yard or more high, and in February it develops its flower-spikes; these are short, horizontal or turned suddenly at right angles just above ground, projecting outward about a foot and clothed with bright crimson tubular flowers from one to two inches long. A well-grown specimen in a shallow pot a foot across will produce half a dozen flower-spikes, which last in perfect condition several weeks. There are also two hybrids between this species and *P. Altensteinii*, which were raised by continental growers a few years ago and which possess most of the good points of *P. corallina*. This species is a native of Colombia, whence it was introduced by Monsieur Linden in 1874.

**CYCLAMEN PERSICUM PAPILIO.**—I mentioned this new sport a few weeks ago, when examples were submitted to the Royal Horticultural Society by the raiser, Monsieur Vervaene de Langhe, the Brussels nurseryman. He has lately forwarded a collection of the flowers to Kew, together with an account of the origin and development of the sport. Twelve years ago he started to select and breed the Persian Cyclamen for an improved leaf coloration. Among the seedlings thus obtained he observed one which showed broad horizontal petals with crisp margins. These characters were reproduced in the seedlings obtained from this sport, but they were all mauve-colored. To get variety of color he crossed them with other colors and selected the best from the progeny, breeding from these again. He has now numerous seedlings of varying shades of color from

white to purple, and all showing the peculiar pose and crispness of petal which distinguishes this from all other sports obtained from the Persian Cyclamen. Either we are better acquainted with the cultural requirements of this plant than we used to be, or, what is more likely, breeders have improved the constitution of the plant by crossing and selecting, for it is cultivated with far more success than formerly, some growers producing easily in about twelve months from seeds plants which twenty years ago would have been considered miracles by the most expert growers.

London.

W. Watson.

## Plant Notes.

**BEGONIA LYNCHIANA** was introduced from Colombia about 1877 by Monsieur Roezl, who sent it to Monsieur Bernary, of Erfurt, Germany. It was distributed under the name of *B. Roezlii*, but as there was already a *Begonia* of that name, Sir Joseph Hooker renamed it in compliment to Mr. Lynch, the curator at Cambridge, who had been the means of its becoming known in England. Mr. John Coulson, of Worcester, Massachusetts, says that he has grown *B. Lynchiana* from the original stock of Bernary and finds that it is almost the same as *B. semperflorens gigantea rosea*.

**BEGONIA SEMPERFLORENS GIGANTEA ROSEA** is one of Lemoine's hybrids introduced in 1888, being a cross between *B. semperflorens* and *B. Lynchiana*. It is one of the very best greenhouse plants we have, has beautiful deep green foliage, and produces an abundance of flowers of a rich shade of rosy red. As it flowers from October to May, it is especially valuable for winter decoration of all kinds. I am of the opinion that the hybrid has almost reverted back to *B. Lynchiana*, or that the *sempperflorens* type has not entered sufficiently into the cross to enable us to keep them distinct. A description of this hybrid, from plants growing at Cornell, is appended:

Rootstock woody, stems succulent, about three feet high, smooth, green. Leaves on short petioles, ovate or reniform, toothed at the margins, about seven inches across, bright green, with a spot of red at the base of the sinus, tinged with red on the under side. Peduncles axillary, stout, four to eight inches long, bearing large panicles (six to eight inches in diameter), of large rosy red flowers. Males with two ovate petals three-quarters to one inch across; females with two to four petals somewhat smaller, ovary three-angled with broad rounded wings. We are able to determine no greater difference between *Begonia Lynchiana* and the *Gigantea rosea* than would occur between plants arising from the same stock. For further information regarding these plants, I would refer to *Botanical Magazine*, t. 6758; *Journal Royal Horticultural Society*, xv., 15, January, 1893; *Regel Gartenflora*, 1876, page 194, plate 871; *Nicholson Dict. Gar.*; *The Garden*, xxiv., page 162, plate 402; xxv., pages 489 and 534; xxvii., page 417; xxix., page 206; *Gardeners' Chronicle*, 1884, page 774; *GARDEN AND FOREST*, ii., page 113, March 6th, 1889; *American Gardening*, xv., page 346, October 12th, 1895.

## Cultural Department.

### American Trees for Ornamental Planting.

AT the meeting of the Lenox Horticultural Society, on the 4th of March, Mr. B. M. Watson, of the Bussey Institute, read a paper entitled "Some Native Trees and Shrubs," in which he commended many of the wild plants growing about the Berkshire Hills as in every respect equal, and oftentimes superior, to imported garden shrubs and trees. He invited attention to the fact that the Arnold Arboretum was a living museum of the woody plants hardy in eastern Massachusetts, and that the plantations had now reached a stage of growth from which it is possible to learn many useful lessons. It offers, at least, an opportunity to study our native trees and compare them with each other and with those from other countries. Many foreign trees, like the Scotch and Austrian Pines, the English Oak and the Sycamore Maple, which had been largely planted in this country, do not thrive under New England conditions. European Beeches, White Willows and many Japanese and Asiatic trees and shrubs are thoroughly

adapted to our soil and climate, and some of them harmonize with native species which have not been generally planted, and which, indeed, it has been difficult to obtain because nurserymen have not kept them on sale, and it has been harder to obtain many native shrubs and trees than to secure plants from distant continents. Fortunately, American nurserymen are now giving greater attention to our needs in this direction, they are propagating our native trees in quantities, and the supply promises to be abundant. In speaking of native trees for ornamental planting, Mr. Watson omitted many of our best trees because they have been largely planted and their qualities are well known. Among these are the Sugar Maple, the Buckeyes, the Tulip-tree, the Chestnut, Catalpa, Elms, Ashes, Kentucky Coffee-tree, Box Elders, Hop Horn-

its red flowers and fruits, together with the yellow "pussies" of the Willow, give distinct warmth to the landscape in early spring. *Acer spicatum*, the Mountain Maple, is a small tree and often a tall shrub in the north, with a good habit of growth. The coloring of its abundant fruit in early autumn is very interesting. It succeeds well in partial shade, and is a good plant for any use wherever a rapid-growing tree of moderate size is needed.

*Amelanchier Canadensis*, the Shad-bush, in all its forms, is a thoroughly good plant. It gives a mass of flowers in early May, and when well grown it makes a symmetrical small tree. The fruit is edible, and its foliage is interesting at all seasons, although it is sometimes attacked by the cluster-cup, a fungous growth, against which no remedy is as yet known. This

Fig. 14.—*Pinus palustris*, near Bordeaux, France.—See page 112.

beams, Poplars, Locusts, Prickly Ash, with all the conifers and broad-leaved evergreens; but I send in a condensed form some of his notes on certain trees which ought to be more widely used, omitting the shrubs for the present.

The Scarlet Maple, or Swamp Maple, is a smaller tree than the Sugar Maple; it is of slow growth, sturdy habit and good proportions, suitable for either swampy or well-drained ground, although it is usually found in the former situation. Its special merits are its scarlet flowers in very early spring, which are followed by scarlet fruit, while in autumn its foliage is of the brightest yellow and scarlet. Its bright scarlet twigs in winter should also be noticed. It is an admirable tree for the borders of ponds and along the banks of streams. A most pleasing effect can be obtained by planting it with the White Willow, as

plant varies widely in form and size, some varieties being low shrubs, while others make sturdy trees forty feet or more in height.

The Canoe Birch is somewhat slow in showing its pure white bark, but when this feature comes it remains, and the tree is a long-lived one. The glittering trunk and the airy head of the mature trees give them an especial beauty. The Yellow Birch is a sturdy, broad-headed tree with lustrous bark. The Black Birch, with its fragrant branchlets, its beautiful aments in the spring and its clear green foliage, is attractive all the year round. The Red Birch has a richly colored bark, and all are trees of singular grace and beauty, and have a certain distinction which adapts them for use in the most pretentious parks.

*Cercis Canadensis*, the Judas-tree, is better known in cultivation than many of the trees of our native forest, and it is a first-rate small tree for planting among larger ones in open spaces or on the borders of heavy woods. This, together with *Cornus florida*, the Flowering Dogwood, succeeds admirably in such a position where there is abundant light or air, and both flower abundantly in the early season. No imported trees equal them for such positions.

*Cladrastis lutea*, the Yellow-wood, is also well known to us in cultivation, and is really one of the best of our trees of medium size. It combines symmetrical growth, fine foliage and handsome flowers. It is particularly good when used as a single specimen. One peculiarity should be noticed, and that is, the trunk often divides near the ground, and this is a source of danger, as the tree sometimes splits apart. One of the stems should be removed when the tree is small, so that the other one can develop symmetrically, or the two should be firmly bolted together.

The American Hawthorns are all useful at every season, and *Cratægus cordata*, *C. coccinea*, *C. tomentosa* and *C. crus-galli* are all good where showy fruit is desired in autumn and early winter. They will make impenetrable thickets where needed, and perhaps they would make better hedges than the famous English Hawthorn. Without enlarging on the special beauties of form and fruit and foliage in each, it is worth saying that they are all admirable trees for parks and gardens either in masses or in single specimens. Our American Beech is not planted nearly as often as the Purple Beech, a variety of the European species, but its fine trunk and singularly smooth gray bark ought to commend it to every planter. *Magnolia macrophylla* is rarely found in northern gardens and shrubberies, perhaps because it is difficult to carry through its first few years. When once established, however, it seems to be thoroughly hardy here in Massachusetts, and gives great satisfaction. The flowers are often more than twelve inches in diameter and the leaves more than two feet long. It is altogether the showiest and most tropical in appearance of any of our hardy trees. It does best in soil containing peat, and is benefited by copious waterings in hot July and August weather. All *Magnolias* thrive in peaty soil, and the best Chinese *Magnolias* I know are growing in a well-drained and protected swamp.

The American Crab Apple is not only one of the best of the flowering Apples now so justly popular, but when compared with the better-known *Pyrus spectabilis* and *Pyrus floribunda* and their varieties, it has two peculiarities worth mentioning. The first is the lateness of its flowering time, which comes from ten to fifteen days after other apple blossoms have formed; and, secondly, the exquisite perfume of its flowers. These peculiarities are both desirable and ought to commend this much neglected tree.

The Sassafras is one of the most attractive trees in our forest. In eastern Massachusetts large specimens are rare, because it is said that the early settlers dug them up so as to export the roots and bark, from which they derived a considerable income. Here along the Connecticut valley, however, there are some noble specimens. The Sassafras is not a hard tree to grow and responds quickly to kind treatment and good soil, and its distinct form and dark green foliage, its well-proportioned head and general clean appearance make it highly desirable.

The Bald Cypress, *Taxodium distichum*, is a tree of striking individuality. Unfortunately, it is somewhat tender in New England, but if set in a sheltered place and some extra care is given to it when first planted it can be grown to fair size, say thirty feet in height or more, and a ripe age. The foliage is most graceful and pleasing in color.

Our common American Linden, or Basswood, and the Southern Linden, *Tilia heterophylla*, when compared with the more commonly planted European Lindens, are certainly more desirable. The native trees are better on account of their larger and handsomer foliage, which does not fall as early in the autumn as that of its European relatives, and its flowers come later. These are clean, wholesome trees which are beautiful all the season through.

The Hickories are said to be slow-growing trees, but in the Arboretum I have observed that for the first ten years or so their growth compares favorably with that of our other hardwooded trees. The Shell-bark Hickory, the Big Shell-bark and the Bitternut have attained a height of from twelve to sixteen feet in ten or twelve years and, as yet, show no signs of stopping. Much is due, perhaps, to the care with which they are treated. The plants are grown from seeds in boxes in the greenhouse, and thus they develop fibrous roots in great quantity. They are permanently planted in carefully prepared soil

when less than a foot high. Nurse plants of native shrubs are provided to give them protection, and these are cut as soon as they interfere with the growth of the trees, a treatment which ought also to be given to our Oaks and the Beech. A well-grown Hickory is a tree of great dignity and beauty, and yet very few of them have been planted in American parks.

American Oaks also have the reputation of being slow growers, but this is not deserved, except in the case of a few species. The White Oak and the Bur Oak, especially its variety *olivæformis*, are certainly not rapid growers. The Scarlet Oak is moderately slow in its early stages, but it is so attractive in its autumnal foliage that this fault, if it is a fault, must be overlooked. The Black Oak develops rapidly, and the Swamp White Oak, although not among the most rapid growers, is a finely shaped tree and always interesting in bark and foliage. The Laurel Oak is perfectly hardy in the Arboretum, and is a most interesting tree with bright, glossy leaves, long and lanceolate, which give it a distinct look and distinguish it from all other species. It is better for New England planting than the Willow Oak on account of the tenderness of the latter tree. The Pin Oak is one of the most rapid-growing species, and it is one of the most beautiful. It is distinguished by its fine and symmetrical proportions and its bright glossy foliage. Although it lacks the beauty of many other Oaks in autumnal coloring, it is so good for every other purpose that it can hardly be planted amiss. The Chestnut Oak grows well. It has admirable foliage, distinct and clean, of beautiful shape and color. The Red Oak, *Quercus rubra*, is a noble tree, and, at least in its earlier stages, is a most rapid grower. Acorns planted in the autumn of 1895 made seedlings two feet high in the summer of 1896. The average growth of some hundred plants was over eighteen inches. Of course, this was in well-prepared soil. In the open ground the safest way, undoubtedly, is to plant it in boxes and thus secure fibrous roots. The Red Oak is one of our largest trees and is distinguished by rare beauty of form and foliage. It is the most satisfactory, perhaps, of all the Oaks for planting singly in avenues or in masses. Of course, it is hard to use Oaks for street planting, inasmuch as trees from ten to fifteen feet high are required, but with care and frequent transplanting in the nursery this can be accomplished, and for this use the Red Oak, the Pin Oak, the Chestnut Oak and the Black Oak are to be recommended in the order given.

It will not answer to treat our trees carelessly because they are native. The soil should be prepared for the commonest of our native plants with the same care that we would exercise if we were planting some high-priced novelties from Manchuria. Much depends on having a deep, rich loam, containing organic matter—humus in the form of peat, leaf-mold or well-rotted barnyard manure—which will tide newly set plants through the first few years of their life, and especially through our hot July and August weather. It is also generally desirable to use as far as possible small or moderate-sized plants. Of course, the immediate effect is not as striking as when larger trees are used, but the first cost and the percentage of loss is much smaller, and the result at the end of five years or so is usually much more satisfactory.

Lenox, Mass.

### Cymbidiums.

THE complaint is often heard that Orchids as a family are far from being ornamental when not in flower, and to the ordinary observer there is nothing to be admired in a house of Cattleyas when the plants are not in bloom, although to the cultivator or connoisseur there is not a day in the year when these plants are devoid of interest. The charge of looking ugly or commonplace cannot be brought against the Cymbidiums as a genus, for even when not in flower they are striking in appearance, especially when seen as large specimens, and many of the species last so long when in bloom that they are among the most decorative of garden plants. There are no difficult subjects in this genus. All of them are terrestrial plants and require a compost that has a basis of loam with enough Fern fibre and broken bricks to make it porous, and they can be easily grown in a moderately cool house. A minimum temperature of fifty degrees in cold weather will suit them better than a higher one, for we have observed that to make some of the species, such as *C. Lowianum* and *C. giganteum*, flower freely it is best, after the growing period in fall, to keep them somewhat drier and cooler, to prevent a tendency to start into a second growth, which invariably prevents the production of a full quota of strong flower-spikes.

*Cymbidium eburneo-Lowianum* is a plant of hybrid origin, as its specific name indicates, and it was originally distributed by the Messrs. Veitch some eight years ago. As it is the off-

spring of two of the best-known species it is regarded as a triumph of the hybridist's skill. A short time since Mr. George MacWilliam, of Whitinsville, Massachusetts, received a first-class certificate for two plants exhibited before the Massachusetts Horticultural Society of this same cross which showed marked differences from the Veitchian hybrid as shown by the colored figure in *The Garden* of October 5th, 1895. This improvement is not surprising, as the parents were both very fine forms of the two species, and the brighter coloring of the petals and sepals and greater portion of the lip, that is colored bright red, marks these two plants as distinct improvements on the original as figured by Mr. Moon in *The Garden*. Mr. MacWilliam states that the plants are but four years old from seed, and while only two have flowered this season out of the great number he has raised from the pod of seeds, many more will probably be strong enough next winter, and it will be interesting to mark the variation in the individuals, if there is any. This clever hybridist has found that no two individuals can be depended upon to come alike from the same seed pod, the variation being great, both in the plant and flower. Another remarkable fact concerning the seedling *Cymbidiums* is, that while the strongest have flowered this winter there are many tiny plants just appearing on the benches and on various pots that are obviously from the seeds sown at the same time.

There are many surprises always in store for the hybridizer, and the interest that attaches to a lot of seedling Orchids cannot be described in words. It has just been demonstrated by Messrs. Veitch that albinos occur among Orchids raised from seeds produced by colored parents, as in *Lælio-Cattleya Decia alba*, figured in *The Gardeners' Chronicle* (February 20th, p. 121), and another clever operator has shown that albinos can be produced true from their own seed. Mr. Cookson has raised *Cypripedium Lawrenceanum* Hyeum from seed, and the plant has flowers that are even larger than those of its parent. It is a form of *C. Lawrenceanum* without the purple in the flower, the white and pea-green giving a beautiful effect, and it will be an inducement for hybridizers to attempt to reproduce the exquisite yellow *C. insigne* Sanderæ true to itself rather than to adulterate it with foreign color.

South Lancaster, Mass.

E. O. Orpet.

#### Notes from the Botanic Garden of Smith College.

ALTHOUGH the Japanese Red-bud, *Cercis Chinensis*, winter-kills badly in this neighborhood unless it is well protected, it is one of the best shrubs we have tried for forcing. It is just now (March 1st) one of the most conspicuous objects in a cool greenhouse; the lovely pink blossoms are larger than those of our native Red-bud, and are borne in greater profusion. Our plants were lifted and potted last fall and stored away in a deep frame until three weeks ago, when they were brought into the greenhouse. Another good plant for this purpose is *Berberis aquifolia*. We use the same plants every winter, and they are producing twice as many blossoms now as they did three winters ago, which was the first winter we tried them. *Magnolia stellata* forces well, but the blossoms do not last more than four or five days. *M. fuscata*, an evergreen species from China, is just coming into flower. *Daphne Cneorum* is one of the very best plants we have for forcing. The sweet-scented pink flowers are borne in terminal clusters on each of its many branches.

Among herbaceous plants now in flower none are more beautiful or make better potted plants than the common Bleeding-heart, *Dicentra spectabilis*. The English Wallflower and Brompton Stocks are in full bloom and are very sweet. Seeds of both were sown last April, and the plants grown on in pots all summer. Auriculas grown from seed sown last April have produced good-sized blossoms, some measuring one and a half inches in diameter.

Northampton, Mass.

Edward J. Canning.

*Cypripedium spectabile*.—I once saw a remarkable display of this beautiful pink and white Lady's-slipper in Minnesota. At the foot of a little hill, overshadowed by the boughs of trees and watered by a trickling rill on one side and a reedy lake on the other, was a small peninsula that was completely covered with tall, rank *Cypripediums* in full bloom. The curious inflated flowers, flamed and rayed with clearest pink-purple, were the largest I had ever seen, the foliage the most luxuriant, and the plants the tallest. The spectacle presented by scores upon scores of these great flowers lighting up the wilderness which man had rarely penetrated was really magnificent. And can we not here find a hint for those so fortunate as to possess shady grounds sloping down to a brook or pond? Wherever this queen of our native Orchids is yet to be found it can be

naturalized in some such appropriate nook in the garden. Plants can be removed from their native haunts in spring and summer with tolerable success, if the transplanting is done with care. But they will be thriftier and more apt to live if moved in autumn while the plants are dormant. The wide, plaited leaf is so peculiar that it is easily recognizable, even when hanging limp and brown on the dead stalk. In places where wild plants are not available the roots can now be bought in quantity at reasonable prices.

Pineville, Mo.

Lora S. La Mance.

*Cypripedium insigne*, var. *Mutchianum*.—This plant seems to deserve a varietal name for its distinct and beautiful form, its great size, firm texture and prominent markings. It appeared among a group of the popular *Cypripedium insigne montanum* in Mr. J. E. Rothwell's collection at Brookline, Massachusetts, and he has dedicated it to his gardener, who maintains a large collection of *Cypripediums* in vigorous health. The most distinct characteristic of the flower of the new plant is its long dorsal sepal, fully half of which is pure white, the basilar portion being studded with deep chocolate-colored spots surrounded with numerous smaller spots of the same color. The inferior sepal is pea-green, sparingly spotted with light brown; the petals have thick lines of spots, deep brown in color, which become obscure near the extremities; the pouch is yellow, with a light bronze suffusion, the staminode being rich shining yellow. It is one of the many desirable varieties of this popular Orchid, and is represented by a fine well-grown specimen.

*Cypripedium Leeannum*, var. *Zenobia*.—This is closely allied to *Cypripedium Leeannum delicatum*, a hybrid obtained from *C. insigne* Sanderæ and *C. Leeannum*. It differs, however, from any yet flowered by its almost white dorsal sepal, a few lines of very minute spots radiating from the base and two lines of light reddish spots running through the centre; the petals are very pale yellow, with rows of small reddish brown spots, the tips being absolutely pure white; the labellum is bright yellow with a faint brown suffusion; the staminode is clear lemon-yellow. It flowered for the first time in the collection of J. E. Rothwell, Esq., Brookline, Massachusetts, among a group of plants of unrecorded parentage, and although many of the finest existing varieties are grown here, this is the most striking of those which have yet flowered.

New York.

A. Dimmock.

**Removal of Greenhouse Shading.**—When the naphtha-white-lead mixture is used for shading greenhouses it is often difficult to remove the lead, since it adheres tenaciously to the glass. If the lead used be unadulterated it may be softened and in part removed by an application of diluted vinegar or acetic acid. This acid converts the basic carbonate (white lead) into the soluble acetate, part of which dissolves and runs away, while the remainder can be more easily rubbed off if still wet. It was found by experiment that a mixture of about one part vinegar to four of water was very successful, and that the solution could be used effectively several times, depending upon the strength of the vinegar. If the lead has been adulterated with barium sulphate, the common adulterant, the barium will peel off of itself or can be more easily removed by scraping than when the lead is pure. Barium sulphate will not yield to the vinegar, since it is very insoluble.

### Notes from Gardens in Brookline, Massachusetts.

To the Editor of GARDEN AND FOREST:

Sir,—Brookline, Massachusetts, has long been noted for its community of interesting gardens. A visit at this season of the year is naturally confined to the inspection of the many interesting collections of plants under glass, although beautiful trees and shrubs are not without attraction even in winter.

Professor Sargent's remarkable collection of Indian Azaleas here is yet in winter quarters in deep pits, except a few plants of the earlier varieties, which are being brought into bloom by gentle forcing. The season will thus begin now, and continue through the splendid display in May and June, and a few will be held until July. *Imantophyllums* have done well here this year and wherever I have seen them. These evergreen *Amaryllids* have always seemed coarse to me, but it must be admitted that well-bloomed specimens of the deeper orange-flowered varieties are handsome, and their colors combine effectively when properly used. They are

here set on the ground level, and thus appear to good advantage. This appears to be the best season to bring them into flower, for I have noticed when they have been held in check in cool houses to retard the flowering season they have not done so well. Mr. Harris, gardener to Mr. H. H. Hunnewell, tells me when they have been advanced in cool houses to the bud stage, and are then taken into warmer quarters to bloom, they expand to almost twice the size they would be if grown continuously cool. Mr. Sanders, gardener for Professor Sargent, is an enthusiast in growing Begonias. A selected seedling from *B. insignis* shows up remarkably well in this large collection, and compared with the type is far more ornamental. A handsome plant of *B. Ferdinand de Lesseps*, a shrubby greenhouse hybrid, has made wonderful growth. It is a summer bloomer, and later will be a mass of white flowers. *Streptocarpus Wendlandii* is just coming into bloom here. Like some of the older varieties, it produces only a single leaf, but of very large size. The leaf itself is not without beauty, and, reflexing, gives the plant a peculiar one-sided appearance. The flowers, however, are neither as large nor as handsome as one would expect, and are, in fact, smaller than those of the newer hybrids. The Cherokee Roses, already in bloom, give promise of hundreds of flowers each day in the near future. The large single white flowers are really handsome, and it is surprising that such a lovely Rose is not more generally grown as a cool-house climber in the north. Some of the retail florists have tried it, but it does not seem to satisfy the popular taste, which prefers double flowers. Some new hybrid *Hippeastrums*, recently imported, look promising in one of the houses, and some are already in bloom. The elimination of the green band is nearly complete, and shows what careful hybridization can accomplish. A pan of the white Grape Hyacinth, *Muscari botryoides*, var. *alba*, was perfection itself. These less common bulbs grown in this way are very effective. In the grounds I noted one of the original plants of *Berberis Thunbergii*, now a bush about nine feet in diameter and five feet high, and about fifteen years old. It is in excellent health and shows its value for permanent planting.

At Dr. Weld's place I found a fine collection of stove tropical plants. That handsome, but deadly, Aroid, *Dieffenbachia*, is here represented by several handsome plants. This native of tropical South America is valuable on account of its luxuriantly spotted foliage. Among the most highly ornamental plants seen here is *Heliconia aurea striata*, with large Maranta-like foliage, striped and spotted with yellow. It is allied to the Banana family. *Licuala grandis*, a rare and beautiful Palm from the South Sea Islands, makes a beautiful display here. Until it was recently rediscovered in limited numbers, the large plant in the collection of Mr. H. H. Hunnewell was one of only four or five known in cultivation. The beauty of its almost circular and purely palmate leaves is not approached by any species of the entire Palm family. *Pavetta Borbonica* is a beautiful foliage plant of slow growth, and resembles a dark green spotted *Ficus*, with opposite leaves. It is allied to the *Ixora*. Other plants noted in Dr. Weld's houses were specimens of *Dracena gracilis*, a distinct and beautiful species with long, narrow, recurving foliage, slightly tinted with purple. Its value lies in its distinctness. *Cypripediums* are among the few greenhouse Orchids with handsome foliage. They are here represented by some beautiful pans of *C. Lawrenceanum* and *C. callosum*, besides a varied general collection. *Curmeria* (*Homalomena*) *Wallisii*, a noteworthy plant, looked like a dwarf *Dieffenbachia*, but on close inspection we find the leaves are leathery, its stems are different, and it is of much slower growth and difficult to cultivate. A splendid show of *Cinerarias* and *Cyclamens* makes one house bright with color, while some standard plants of *Acacia pubescens* and *A. heterophylla* serve to relieve what would otherwise be a surfeiting impression, for some of these gorgeous displays seem almost too showy. Among the *Cyclamens* are such good varieties as *Rosy Morn*, *Alba magnifica*, *Mont Blanc* and *Brilliant*.

### The Rotation of Species of Trees Under Forest Conditions.

To the Editor of GARDEN AND FOREST:

Sir,—Considerable discussion has been occasioned by the questions in regard to reforestation in the first report of the Chief Fire Warden of Minnesota. This problem of forest perpetuation and forest rotation is an interesting study. The opinion often stated is that the natural rotation in species of

forest trees is a necessary result of an impoverished condition of the soil; that one species or family takes a different food from another, and after one species has taken the nutriment it prefers there is not enough food remaining for a second crop, so that another kind steps in, a kind that relishes and thrives upon the plant-food that remains. But this idea of soil impoverishment under natural forest conditions is in opposition to all modern teaching. It is held, nowadays, that the forest is a restorer of plant-food, so that one crop of trees leaves the soil better for having sustained it. Forest rotation or the succession of species is not, therefore, sustained by the theory of deficient nourishment. Even if we were to specialize and attribute the phenomenon to a single ingredient of plant-food, the hypothesis would still be inadequate, for all classes of forest trees take the same foods in slightly varying proportions only.

But if variation in the condition of the soil does not serve the purpose, will a consideration of the tree's reproductive organs solve the problem? The Pine family is capable of producing, and frequently does produce, an abundant seed crop. Failure to reproduce itself cannot then be attributed to lack of seed-production. Are these seeds prepared to withstand adverse conditions? No, they have no hard nutty covering as do those of the Oaks and Hickories. The seed, while provided with wings to facilitate its transportation, soon loses its vitality if exposed even to the conditions of the natural forest. In other words, the Pine seed must find congenial surroundings for germination soon after it is shed from the cone, or it perishes. Pines do not produce seed each year in succession, and consequently the loss of the seed crop of one season may delay a stand of young seedlings for several years. Young seedlings of most trees are tender as regards adverse surroundings, and this is especially true of the Pine. When favorably lodged, however, the seeds of the Pine germinate readily and the young seedlings thrive under proper conditions of shade and the like, but with our lack of system in forest management these congenial conditions for germinating the seed and developing the young seedlings are rarely provided. When a propitious environment chances to be present, the White Pine reproduces itself readily.

Since, then, other species are more commonly the successors of the Pine than its own kind, it stands to reason that the conditions have been too severe for the reproduction of the Pine. It is also an indication that other species are more virile than the Pine. Is there in nature any reason for this? If the theory of a natural progression from the lower to higher forms in the organic world is to be maintained, there is ample reason for these peculiarities of rotation or succession of species.

According to Gray, the Pines are the oldest representatives of our forest flora. The giant *Sequoia* is a lone survivor of a great, and at one time numerous, group of plants. The *Ginkgo*, a native of the orient, is at present reduced to the stand of a monotype species. Formerly it undoubtedly had many coördinates. The *Sequoia*, the *Ginkgo* and the Pines all belong to the same general scattered family of *Coniferae*. It is known that there are among this family representatives of once prosperous genera. What does this mean? Simply this, that the great order *Coniferae* is slowly and gradually losing ground in the natural competition for supremacy. They are, in other words, less virile than many of their competitors. More congenial conditions for growth and development must be provided for them than for other species with which they now have to contend. Then, again, if we examine the structure of the floral or reproductive apparatus of the Pine we find it less highly developed than the same organs in their more successful rivals. This indicates that the Pine is less highly organized than other trees. The more highly a plant or animal is organized, or the more complex its differentiation, the more capable it becomes of adapting itself to slightly changed conditions. The low position in the scale occupied by the Pine, to an extent, explains why it does not reproduce itself. In fact this, to my mind, is the keynote to the whole situation, for all necessary adaptive variations are limited by the station occupied by the plant.

If what has been stated is true, and the White Pine requires extra care in order to induce it to perpetuate itself, then it is our business as lumbermen and foresters to study those conditions and plan to conduct our operations so as to maintain the proper soil, shade, moisture and other conditions suited to the growth of this most valuable forest-tree.

Substitutions for this timber are constantly being tried, but for some purposes the White Pine is greatly preferred to other woods, and it will always be in demand.

West Virginia University, Morgantown, W. Va.

## Bibliographical Notes on American Trees.—I.

To the Editor of GARDEN AND FOREST:

Sir,—That elaborate contribution to dendrological bibliography which Mr. George B. Sudworth has lately offered, in Bulletin 14 of the United States Department of Agriculture, cannot fail to be received as a standard manual of the nomenclature of our trees. It is, therefore, important that errors be pointed out as promptly as may be that other writers may avoid repeating them; and from an examination of a few of the earlier pages of the volume I infer that these errors may prove somewhat numerous. Mr. Sudworth seems to have neglected a considerable number of books which might profitably have been consulted by one who is to give a list of our trees, with nomenclature and citations correct, under the rules adopted in this work. For example, *Larix*, as a genus distinct from the Linnæan *Pinus*, is attributed to Adanson (1763), whereas two important dendrological authors restored the genus within the first decade after 1753, namely, Miller in 1759, and Duhamel in 1755. *Abies* is still farther from being attributable to Jussieu and the year 1789. It was maintained by Hill as early as 1756, and even a year earlier than that by Duhamel, so that to this last-named author belong both *Larix* and *Abies* as post-Linnæan genera. And here let me observe that Dr. Britton's *Illustrated Flora* is in need of the same corrections here indicated.

That *Picea rubra* can hardly be maintained for our Red Spruce has lately been suggested by Mr. Jack (GARDEN AND FOREST, vol. x., 62-64); but the reasons for the retirement of this name, under the rules by which Mr. Sudworth and others guide themselves, are more numerous than Mr. Jack has shown. I suppose that a too implicit trusting to the *Index Kewensis* has hindered our authors from discovering that the *Abies rubra* of Poiret was at the time of its publication a mere homonym. Even on an earlier page of Poiret this name occurs as a pre-Linnæan synonym of *A. excelsa*, Poir. But that which, under the rules alluded to, completely invalidates the specific name *rubra* for any American tree of this group is the fact that, only three years after 1753, Hill published the common European Spruce as *Abies rubra*, so that *Picea rubra* fails of applicability to any tree of our country, for the reason that it really belongs, under said rules, to that which is now generally known as *P. excelsa*.

Catholic University, D. C.

Edward L. Greene.

## Recent Publications.

*A Manual and Dictionary of the Flowering Plants and Ferns.* By J. C. Willis, M.A., Director of the Royal Botanic Gardens at Ceylon. Cambridge, England. 1897.

This work consists of two parts, the principal one being vol. ii., which is an arrangement in the alphabetical order of their Latin names of all the classes, cohorts and natural orders of plants, besides several thousand genera, including all the British genera, the greater part of the common European and American genera and the principal southern and tropical genera. This volume comprises 428 compactly printed duodecimo pages. Vol. i. is shorter, consisting of little more than 200 pages, and at the outset it was intended, the author says, as a sort of supplement or index to the dictionary. But it was found necessary to broaden this scheme, so that it appears now as a fairly complete treatise on the morphology, classification, natural history and geographical distribution of plants. Mr. Willis justifies the preparation of this part of the book in its present form by the fact that there was really no good text-book on the natural history of plants or their geographical distribution available in English, the morphology in such books as exist being out of date and not based upon evolution. The principles of classification and of evolution are not explained in elementary English text-books on the ground that they are too abstruse, and in advanced books it is taken for granted that students are already familiar with them. But, notwithstanding the form of this little treatise, the original design of it is preserved, so that it well serves the purpose of cross reference to the classified list in Part ii., while as a text-book it may also be expanded to almost any degree by referring for details to Part ii. Besides the mere names, this alphabetical list, by a system of abbreviation and condensation, contains a vast amount of information. The families of plants

are treated with much more fullness than in ordinary systematic botanies, while the genera are discussed more briefly, except in cases where they have characters of special interest which distinguish them from the rest of the family. The book would be better if it contained more illustrations, but floral diagrams of the larger families will be found and other figures which illustrate difficult groups within the families. Genera which have economic uses are very fully catalogued, although the products and methods of obtaining them are not generally given. The general arrangement is that of Engler, although sufficient reference is made to the classification of Bentham and Hooker to enable any one to use that system. The nomenclature is chiefly that of the *Index Kewensis*, and the more common and important synonyms of the different genera are given. Altogether, the little book will be very useful to students to whom works of general reference are not available. Even when they are, their bulk as well as their antiquity makes it troublesome to use them. Of course, such detailed information as may be required by specialists is not to be looked for here, but the beginner will find what he needs upon most subjects which do not require the use of a microscope.

Mr. Willis's book is one of the useful Cambridge Natural Science Manuals, and it belongs to the Biological Series which has been prepared under the general editorial supervision of Arthur E. Shipley, M.A., Fellow and Tutor of Christ's College.

## Notes.

The colors of the fruiterer's stock have not a little to do with its attractiveness, and at this time the deep rich orange of the Navel fruit from California, the paler color of Messina lemons and large, smooth-skinned grape-fruits, and the brilliant red of tiny Lady apples and of large Baldwins make bright spots in displays which include the more neutral-colored mushrooms, pineapples, Winter Nelis and P. Barry pears, Catawba grapes, and what is probably the last importation of English hot-house grapes, each bunch cut with a piece of the stem. Some of the rough-skinned King of Siam oranges, from California, are now offered, and this novel fruit costs \$2.00 a dozen. Other delicacies seen in the windows of fancy-fruit stores are beautiful smooth hot-house tomatoes, perfectly grown cucumbers, blocks of maple-sugar and half-pound pats of "fresh" or unsalted butter done up in white oiled paper, and costing thirty-five cents each.

Mr. George L. Russell recently read an essay before the Board of Trade at Orlando, Florida, on the "Possibilities of Pineapple Culture," which he considers among the most promising of the industries of that state. There is always a demand for the finest fruit. A twelve-inch home-grown sucker will come into bearing in a little more than a year and the structure for properly shading an acre of land need not cost more than \$450. Varieties like the Smooth Cayenne, Golden Queen and others of prime quality attain a size of from six to twelve pounds each, and ought to command at retail in northern markets at least a dollar. One great trouble has heretofore been that the tender fruits are injured in transportation, but a kind of crate has been devised which will hold a dozen fruits of the first size, packed in excelsior so as to prevent their bruising, and they will keep in this way at least a fortnight, which will afford ample time for transportation, even to foreign markets.

An article on seed-sowing in *Vick's Magazine* recommends the scattering of fine hay or the clippings of the lawn, just thick enough to lightly cover the soil, over a bed where seed has recently been sown. The advantage of this is that it breaks the sun's rays and, like any other mulch, prevents the rapid drying out of the soil, especially when the wind blows. But it is particularly useful in preventing the surface of the soil from becoming beaten and patted down by watering or rain. May soils bake after they have been watered, but when the water is sprinkled on so as to filter through the mulch it does not wash the seeds bare nor beat down the surface, and, of course, the shading, too, prevents it from hardening into a brick-like consistency. No general rule can be given as to the depth of sowing seed, and in light sandy soils the covering can be thicker than in those of heavy clay. A seed that has a covering four times as thick as its own diameter is not buried

too deeply, and a simple sifting of soil over the finest kind of seeds after they have been sown upon the surface will suffice, provided the soil is afterward properly pressed against the seed, or "firmed," as it is called. In the case of large seeds gardeners often tramp on the row, and with lighter ones a hoe blade or a block of wood is used for compacting the soil.

The windows in the uptown flower stores make a brave display even during the Lenten season, a comparatively dull trade time. Under the influence of the bright clear weather of these early spring days the masses of bloom show good color and vigor. Sturdy clumps of forget-me-not, the tiny flowers set in abundant foliage, immense pansies of many hues, long stems of lily-of-the-valley, little bunches of yellow primroses, vases of the beautiful blue cornflower, well-grown heliotrope, giant heads of mignonette, and single, and the deeper-colored double, violets are seen in almost all collections. There are also dainty buds of moss roses, great spikes of forced gladiolus and quantities of Easter lilies. White sweet peas make a delicate showing, and one of the windows had a drapery of Swainsonia, the finely cut leaves and clusters of white flowers being peculiarly effective and satisfying. A row of flowering plants of *Amaryllis* set in a bed of green foliage plants made a gorgeous display, the rich red flowers borne on their stout stems, some of them two feet high. Large yellow and white marguerites, double white snapdragon and beautiful pink tulips and many other bulbous flowers added to the variety, with French lilacs, Jacqueminot, American Beauty and other roses. Hardly any potted plants in flower are shown now, these being held in the greenhouses for Easter, and only a few pots of violets were seen, and the quiet flowers nearly hidden in the luxuriant leaves seemed especially fitting at this time.

Bulletin No. 124 of the Cornell University Experiment Station contains particulars of the pistol-case-bearer, an American insect, which has been known for twenty years, but which has never done any serious damage except occasionally in New York and Pennsylvania. The insect is one of those which are encased in a curious-shaped suit after the fashion of the cigar-case-bearer, and this bulletin gives such an interesting description of the habits of the interesting little animal that no intelligent farmer's boy can fail to be interested if he once begins to read it. Professor Slingerland's work does much more, therefore, than give some immediate information about the pest and the methods of fighting it, it helps to encourage "correct and hopeful habits of thought." Experiments seem to show that the insect can be held in check by a spraying of Paris green or the Bordeaux mixture applied very thoroughly. When it is abundant at least two applications should be made before the blossoms open. If the Bordeaux mixture is applied with the Paris green at the second spraying the apple-scab fungus will receive a check, and this period between the setting of the bud and the opening of the flower is just the time when the bud-moth as well as the cigar-case-bearer needs a dose of poison, since all three of these pests often occur together. If any of the pistol-case-bearers are left they can doubtless be poisoned by an application of Paris green made a little while after the petals fall, and this is also the best time to spray for the codlin moth or appleworm. A fruit tree should never be sprayed while it is in blossom.

Mr. John Craig, of the Canadian Experiment Fruit Farm, read a paper recently before the Michigan Fruit Growers' Association, giving an account of some experiments with the different standard varieties of Peaches and Plums, with a view of testing their relative ability to produce fruit after winters of unusual severity. Twigs of the different varieties bearing fruit-buds were taken from a number of localities in the Dominion and examined with a lens, and most of the cions were placed in water in a glass-house where the blossoms were allowed to expand. Of course, the percentage of fruit buds killed on a Peach-tree is not the measure of loss to the crop the ensuing year. If a fruit set for every bud that opened, thinning would be absolutely necessary, and the frosting of some buds might prove a help to the crop. Again, the specimen twigs may have been largely cut from the lower branches of the trees where the temperature is colder at critical periods than at the top of the tree where the greater part of the fruit is found after severe winters. The tables presented, therefore, of the different varieties of Peaches and Plums grouped in relation to the power of their fruit-buds in resisting frost, are merely tentative, although they have some value as a list subject to revision. Several interesting facts, however, were noted. For example, tender fruit-buds are not always associated with tender leaf-buds. As an instance, the Plum Glass Seedling suffers less than most varieties at Ottawa from the

winter-killing of terminal shoots, but it bears no fruit except after very mild winters. Other varieties which have their terminal wood killed back annually, like the Damsons, nevertheless produce fruit regularly on spurs of the older branches. This means that in the north there is much to learn on this subject, and after the selection of varieties of merit and of known hardiness the advice to cultivate so as to encourage the ripening of both wood and fruit-buds is the most practical that can now be given.

The Office of Road Inquiry of the United States Department of Agriculture has published a circular on brick-paving for country roads, which sets forth an experiment made recently by the citizens of Monmouth, Illinois. This vitrified brick, as is well known, is not made of clay, but of a peculiar shale rock, and it is so hard that a sharp-edged fragment of it will cut steel. In accordance with a law which authorized the construction of macadam or other hard roads in Illinois, the land-owners of Monmouth have laid an experimental section of vitrified brick road at a cost of about ninety cents a running foot. The road is eleven feet wide, and on either side of it there is an earth track for use in dry weather, making altogether a road forty feet wide. Stone roads in that region have cost seventy cents a running foot for a track eight or nine feet wide, and, of course, the glazed brick makes a much smoother surface. It is suggested that in many places, for example, where there is a short roadway subjected to very heavy traffic, as about factories, mines and railway stations, two parallel strips of these brick, from sixteen to twenty inches wide, could be laid through the middle of the macadam road and gauged so that the wheels of all kinds of vehicles could follow them. The decreased traction would be as great as if steel rails were laid in the macadam, and if properly set they would last a long time under any traffic where a macadam road is justified. It is also pointed out that these strips of brick pavement would make admirable bicycle tracks.

The Wild Garlic, *Allium vineale*, is not a native of this country, although in Pursh's *American Flora*, published in 1814, it was already reported as common in old fields. It is too well known to need description, and it is one of the most injurious of weeds in the middle Atlantic states; it disfigures lawns; it gives an evil flavor to milk and its products; and, since its bulblets are about the same size as wheat-grains and mature when winter rye and wheat are harvested, these are often ground with the flour and impart a strong flavor to it. Besides this, the bulblets form a varnish-like coating on the rollers of the flour-mills, which makes it necessary to shut down the mill until this gum is washed off. The weed is very difficult of extermination. An acre of land near Germantown, Pennsylvania, was trenched by hand to a depth of three feet, and all the bulbs found were picked out and destroyed, and although the quantity of the Garlic was much reduced, a sufficient number of bulbs escaped to reseed the land within a few years. Hand-pulling just at flowering time is only partially successful, and the cultivation of hoed crops is ineffective by itself. If land is plowed late in the fall, so as to leave the bulbs near the surface and exposed to freezing and thawing, many of them will be killed, and the surviving shoots can be destroyed by spring cultivation, after which oats may be sown or corn can be planted. This process repeated for two years will destroy nearly all the Garlic, and the remaining plants can be exterminated by hand. A bulletin published by the Department of Agriculture gives some very interesting facts in regard to this evil weed, and it recommends, among other remedies, (1) that the soil should be shaved near the surface as often as the shoots appear; (2) that lime should be put liberally on the pastures and meadows to help the grass and crowd out the Garlic, and (3) that hogs should be confined on Garlic patches. It is added that a single drop of carbolic acid on a leaf or shoot will kill the entire plant. Half a teaspoonful of the acid applied so as to strike most of the shoots in a clump as they grow in pastures will kill them all. The cheaper quality of the acid, worth from thirty to forty cents a gallon, is effective, and should be used with little dilution, and applied with a machine-oil can. On the grounds about the White House in Washington, comprising eight acres, an abundant stand of Wild Garlic was nearly all destroyed by a single application of carbolic acid. The cost, including the acid, cans for applying it, and the wages of the boys who did the work, amounted to nearly \$10 an acre. The grass was practically uninjured, and during the following season it covered the spots where the Garlic had been destroyed. To complete eradication by this method the land should be carefully looked over during each of two succeeding years in winter or early spring when the plants are not hidden by other vegetation.

## GARDEN AND FOREST.

PUBLISHED WEEKLY BY

THE GARDEN AND FOREST PUBLISHING CO.

OFFICE: TRIBUNE BUILDING, NEW YORK.

Conducted by . . . . . Professor C. S. SARGENT.

ENTERED AS SECOND-CLASS MATTER AT THE POST-OFFICE AT NEW YORK, N. Y.

NEW YORK, WEDNESDAY, MARCH 31, 1897.

## Garden Design.

LAST November Mr. Inigo Thomas delivered one of his periodical addresses on Garden Art before a London society of architects, and it has been published in successive numbers of *The American Architect and Building News*. This lecture, like the one he delivered a year ago, and which was also republished in this country, is interesting, and to a certain extent instructive, although it contains nothing which had not been said in *The Formal Garden in England*, a book written by Mr. Thomas in collaboration with another young architect, Mr. Reginald R. Blomfield, some half-dozen years ago. Mr. Thomas describes with sympathy some of the old gardens of Italy, of Scotland and of England, and almost induces the reader to share with him a little of the enthusiasm which he thinks he feels over Yews pleached into cubes and obelisks, geometrical designs in Box and compartment gardens. We cannot but agree with him that there was design of these old places, and that even in northern latitudes and in modern days it might be possible, under certain conditions, to connect a garden of this sort with certain kinds of architecture that would be satisfying from many points of view. But Mr. Thomas does not rest here. He continues to deny that there can be anything like art in gardens of any other kind. He theorizes upon the assertion, so often made, that in the very nature of things such an art as landscape-gardening is impossible, and that formal gardens alone show anything like design. This means that one can have a certain narrow architectural training and skill and yet possess no sympathetic appreciation of charming scenery and no feeling for natural beauty. Painters of landscape know that there can be beauty of composition in trees and shrubs and grass naturally arranged, and few people have their sense of beauty so deadened by technical study that they do not enjoy this beauty as it appears in nature. Whenever a planter so models his grounds and so arranges the elements of verdure he employs as to give to the beholder the impression of a beautiful natural group, there can be no question but that he has created a work of art.

The fact is that there is more than one kind of a garden

and that gardens are made to fulfill many different purposes. It is not logical, therefore, to hold that because one kind may be good for a certain restricted use all the other kinds are essentially bad. Of course, there are bad gardens of all kinds, and the most sturdy reactionist would hardly claim that all formal or architectural gardens are good, and we have, therefore, tried to learn what are the essentials of a good garden according to Mr. Thomas. He asserts that he is advocating principles, and the most complete statement of them is found in a passage where he insists primarily on "an enclosure, decided and uncompromising, not of sunk fences or iron palings, but of good honest masonry high enough to cast broad shadows early and late and keep the wind from the flowers and fruit-trees; then subdivisions either by subsidiary walls or hedges of Yew or Box, almost as dense as the masonry itself; then that the proportioning of the surface of the ground has much the same treatment that the designer deals out to the façade of a building." Now, there are many places and many climates where a garden treated on this plan by a genuine artist could be made a most appropriate and attractive addition to a house, but every reader can recall some country place without its high and uncompromising wall which has the same sense of shelter and seclusion by its position and distance from the roadway and its background of foliage, and perhaps its protection of a belt of shrubbery dense enough to serve as a hedge. We know many charming places in America that would be disfigured by a high-walled enclosure with subdivisions as dense as a wall. And yet we should like to see some artist of real creative ability attempt a garden of this kind in connection with a house of some pretensions in America. Formal gardening as it is known here means little more than ribbon lines, or geometrical flower-beds and a straight hedge or two, and it would be an education in garden-art to see an American realization of Mr. Thomas's ideal. We have few opportunities here to see high garden walls such as Mr. Thomas commends. These walls have a genuine use in England, for against them fruit-trees and vines are trained to catch the warmth of the scanty sunshine. We do not train our Pear-trees or Peach-trees on espaliers in this country, and perhaps in our bright sunshine the walls would look hard and staring. Since art is the decoration of a service and never runs counter to common-sense principles or every-day usefulness, it may well be that each country and climate should develop a style of gardening distinctly its own, and we probably should make quite as serious a mistake in adopting the design of a garden which would be beautiful and useful in England as we did in the beginning of the century in using so many of the trees and shrubs which flourish in England, and in not availing ourselves of the treasures of our woods.

But what we set out primarily to notice was an error into which Mr. Thomas falls at the beginning of his address, and which ought not to go uncorrected. His model garden is one of symmetrical spaces whose design bears a decided relation to the architecture of the house. Indeed, he asserts that nothing else is a real garden and that what has passed under that name for nearly a century would have been called a wilderness in better days. But he adds—and here is the error—that the leading purpose and chief interest of planters who use the natural arrangement is to have a "growth of rare shrubs and plants." This is fundamentally false and it shows how superficial Mr. Thomas's information is in regard to landscape-art. The real master of garden-art is not a mere horticulturist nor one who aims to gather a collection of rarities and have a museum of living plants. There are, it is true, enthusiasts who take pride in showing visitors the latest *Cypripedium* or a new Birch from Manchuria that no one else has grown. This passion, however, can exist without the slightest taste in the arrangement of plants or the slightest feeling for the poetical charm of a landscape. To the real master of the natural style of landscape-art the individual plant is only an element in a picture, and it is always subordinate to the

total impression. It is the greatest artist who can produce the most impressive pictures with the commonest material—ordinary shrubs and trees and grass. Indeed, so-called specimen plants have a larger and a more important place in the architectural or formal garden than in the best work of those who attempt to hold the mirror up to nature.

It is a pity that the advocates of formal gardens so generally misrepresent what is the fine art of gardening, for there ought to be no conflict between the so-called schools. The man who creates broad and tranquil pastoral scenery, so that it presents to the imagination pictures of peace, is certainly an artist. The man who in a smaller way treats a bit of ground about a house with a leading motive, so that the picture is a unit in its expression, is certainly as much of an artist as one who makes a perfect balance in the orderly arrangement of his hedges and scroll-work. The latter may be art, too, just as surely as the mingling of colors and forms in an oriental rug is art; but the formal garden addresses the æsthetic sense alone, and if there is a difference in degree it is the nobler art which appeals to something beyond the sense of beauty, and taking the materials which nature gives so groups them as to make a picture with power to stir the feelings and touch the heart.

### The Ideal Grape.

ONE of the strong features of the horticultural teaching at Cornell is the seminary work, which is really a modification of the old lyceum idea. Teachers and students meet together in an informal, half-social way to discuss some topic which is previously agreed upon. The result has been the organization of a club known as the Horticulturists' Lazy Club, and it is provided with a unique and attractive club-room built especially for this use, and connected with the forcing-house. Pictures of horticulturists and botanists, fruit and flowers, diplomas and other subjects relating to the craft are hung about the walls. Here every Monday night from twenty to thirty enthusiastic students meet, Professor Bailey being among the number, and here, too, at all times of the day they find a waiting-place and a meeting-place. There is a growing library in the room, with files of the leading horticultural journals in English, French and German. At each meeting some student makes running comments on the horticultural news in the papers and books, and then the topic for the evening is taken up. This Lazy Club is so democratic that it has no officers and no rules. There is simply a register in which each participant places his name, if he desires to, at each meeting. Near at hand is a storage cellar, in which over thirty varieties of apples have been kept, to enliven the exercises all winter long, and there is always something in the forcing-houses to provoke discussion.

Aside from the stated meetings of the club, a seminary on plant-breeding has been running on Thursday nights during the winter term. The business of this seminary has been to discuss the fifteen rules in chapter iii. of Professor Bailey's *Plant breeding*. The book was used as a text-book in the fall term, but about fifteen advanced students have discussed the questions more at large during the winter. Having finished the fifteen rules and having two meetings of the term left, the seminary took up the question of "Unattained Ideals in the Strawberry and the Grape." The Grape meeting was enriched by letters from Grape experts, one of which, by Mr. T. V. Munson, has been sent to this journal by one of the members of the seminary. The paper is so good that we publish it entire.

#### THE UNATTAINED IDEALS IN THE GRAPE.

When it comes to the practical point of combining all the desired characters in one variety, it is found there are conflicting elements to be worked out first. To render my meaning clear I will mention the characters desired, yet not found combined in any variety in existence, and which quite probably never can be:

1. Vigorous, healthy plant; resistant to fungous diseases

and to phylloxera; hardy to withstand cold and heat north and south; long-lived; prolific; adapted to all tillable soils and aspects.

2. It should ripen a constant full yield, evenly in the cluster, here in the south from June 25th (when the very earliest known varieties begin) until November 1st, or to the time of killing frost.

3. For appearance sake it must bear a good-sized cluster, neither too loose nor too compact, with berries never below medium size (unless in wine grapes, when they may be smaller), persistent to the pedicel, with skin thin, tough, never cracking in changing weather, and in color yellowish green, lively red of various shades, and black, as these shades are always in good demand throughout the entire season.

4. The requirements as to flavor demand a skin non-astringent and non-pungent; a pulp tender, meaty or juicy, yet not "slushy," like that of a berry affected by white rot, as some varieties naturally are, rich in both sugar and acid so as to be sprightly, yet not too tart (Delaware is a little "tame"; Catawba just beneath the skin is excellent, but next the seeds too acid, while the Vinifera class is generally too much like sweetened water in flavor, and Iona at its best is perfection); flavors must be delicate, not musky like the Labruscas, however—a faint touch of this is permissible. (There are peculiar and various very agreeable fruity flavors in our native Post Oak grapes, V. Linsecornii, of Texas, Indian territory and south-west Missouri, which I consider superior to any other native grapes.) The dead, earthy taste found in the after-taste of most Labrusca varieties is to most grape connoisseurs even more objectionable than their "foxiness"; the seeds should be small, soft, few (one to three), and separating readily from the pulp. The sprightliness and flavor should remain in the grape a long time. (The Concord becomes flat here in the south in a few days after it turns black.)

Now, it is clear at once that no one variety will ever be developed to supply all the above requisites. The varieties that ripen in the heat of summer quickly pass away. Two weeks is about the length of time that the best varieties will keep their character, in July and August, although they last much longer in September and October, so that our grape season requires at least five successions of two weeks or more to cover our entire grape season.

The old standard varieties are all gone here by about the first week in August. After that for a month the Rotundifolia varieties come in. I have tried to fill in this gap and have partially succeeded in the varieties named Fern, Lanssel and Marguerite.

Each of the five ripenings should have at least one first-class red, one yellow and one black table grape, to say nothing of wine grapes, thus making at least fifteen varieties to cover the season in the south. For the north one half the number would be sufficient. By comparing the above ideal succession with the actual it will be quickly seen that the field is not occupied by a great deal either north or south, but better in the north than in the south.

If you will endeavor to fill up each square of the following diagram with an ideal grape, as outlined for it above, with nine squares, or a month and a half for the north, say, the latitude of New York, and for fifteen squares or the full season of three months, the deficiencies will at once become apparent:

	BLACK.	RED.	YELLOW.
First ripening, 15 days, . . .	1	2	3
Second ripening, " . . .	4	5	6
Third ripening, " . . .	7	8	9
Fourth ripening, " . . .	10	11	12
Fifth ripening, " . . .	13	14	15

Grapes which are of a green color when ripe are undesirable, so are pale dull red ones such as Perkins, and varieties which ripen unevenly, as the Concord generally does in the south, are almost worthless. The Elvira is a green grape, the Pocklington a yellow grape; the first is far better in quality, but the latter will outsell it on account of color.

When all points constituting the ideal variety for each space are considered, it will be found that nearly, if not quite, all the spaces will be found empty, and this emptiness only shows the work yet to be accomplished by originators.

Let us try a few varieties and see where and how they fit. Space No. 1 will not contain Champion on account of its poor quality and its habit of dropping from the cluster, but it would go in so far as productiveness and size are concerned. Campbell's Early is now being put forward as completely filling it,

but it has not yet been given a practical test in most parts of the country. My Presly, tried in Space 2, fills the requirements fairly as to earliness and vigor, also in color of berry, but it is lacking in size both of cluster and berry, although it is as large as the Delaware; neither is it prolific enough in the weight of fruit, nor of good enough quality, yet it is considerably better than Champion.

In season, Winchell (or Green Mountain) might be applied to Space 6, and would fill it quite well, except that it is too green and too subject to black rot. Niagara might fill the same space (6), and would do fairly well in size, productiveness and vigor at the north, but it is not quite good enough (too foxy), and the skin is too tender for long shipment. And so we might go on through the list and find vast room for future work in originating better varieties and many to occupy spaces yet vacant.

The next question is, what material have we from which to create these needed varieties?

It is very certain that the *Labrusca* varieties alone can never fill the diagram, neither can any other one species; neither can *Labrusca* and *Vinifera* jointly, as will be apparent when you apply all the known simple and hybrid varieties of these; neither can *Labrusca* and *Riparia*, which would take in addition the *Labruscas* in our catalogues and all the *Labrusca* x *Riparia* hybrids, such as Clinton, Taylor, Elvira, etc.; neither *Labrusca*, *Riparia* and *Vinifera*.

But add the large-clustered, large-berried *Vitis Linsecomii*, and we go forward at once to the medium and later seasons, and fill better many of the already partially filled spaces. *V. æstivalis* and *V. Bourquiniana* join well in the work. So will *V. Champini*, *V. Doaniana* and *V. rupestris*, among the extra-early and mid-season varieties for the south, and finally the *V. rotundifolia* will come in for a share in the subtropical Gulf regions. *V. Solonis* in the hot south-west will take the place of the sprightly *V. riparia* of the moist cold north-east. No one generation of simple or hybrid varieties will do the work. It will require generation upon generation, combination upon combination.

I have found that grapes of a certain color, as of red, yellow or black, yield a great majority of their own color in their progeny, and especially so if such colors are crossed or hybridized together, as naturally would be expected; hence, in breeding for color, use only parents of that color if they possess the other desired properties. A careful study of material in hand in connection with above general considerations will lead readily to the minute study of special qualifications; such, at least, has been my experience.

### The Cypress-tree of Tule.

ON page 125 of this issue is the portrait of the Cypress-tree of Santa Maria del Tule, made from a photograph, for which we are indebted to Baron Thielmann, the German Ambassador at Washington. This tree stands on the grounds of the little church in the town of Tule, on the road from Oazaca to Guatemala, by way of Tehuantepec, and is the largest of the Mexican *Taxodiums*, and perhaps the most famous tree in the New World. According to a note in the eleventh volume of Sargent's *Silva of North America* its trunk at five feet above the ground, according to late measurement, has, in following all its sinuosities, a circumference of 146 feet, while the actual girth is 104 feet, the greatest diameter being forty feet and the least twenty feet. Its height is estimated to be 150 feet, and the spread of its branches is 141 feet. As measured by Baron Thielmann last autumn its height was between 160 and 170 feet and its largest diameter forty-two feet. This tree is believed to be two thousand years old. It was mentioned by Humboldt, and his name is inscribed on the bark.

In the third volume of this journal the portrait of another of these wonderful Mexican *Taxodiums* was published on page 155. This was the Cypress of Montezuma, the largest of the great Cypress trees in the gardens of Chapultepec, near the City of Mexico, and a noted tree nearly four centuries ago. The Cypress of Montezuma is a tall and still graceful tree, 170 feet high, with a trunk to which travelers have ascribed a girth varying from forty to nearly fifty feet, these discrepancies being due, no doubt, to the different points above the surface of the ground at which they were made.

The Mexican *Taxodium*, although it grows to a much greater size, is specifically almost identical with the *Taxodium* or Bald Cypress of our southern swamps, being chiefly distinguished from that tree by its autumnal flowers and by the persistence of its leaves, which do not fall in the autumn, and, although most botanists now consider it a distinct species, it may on further investigation prove to be only a geographical form of our tree.

### The Flower Industries of Southern France and Paris.

FROM December till May is the season for the flower industries. It is only within the last fifteen years that the commercial culture of flowers in France has attained its present large proportions. The area now devoted to flower-farms, where entire fields, not beds, are cropped with the most lovely and odoriferous flowers, lies in the area twenty by ten miles in extent which takes in Cannes, Nice and Grasse. The climate as well as the soil are especially suitable to the enterprise in question. Subdivisions of the area have also their peculiar floral outputs. Cannes, Nice and Antibes are reputed for their famous Roses; Grasse for its Jonquils, Violets, Tuberoses, Jasmine, Mignonette; Hyères and Fréjus, for Violets; the suburbs of Cannes, for Pinks. Bulbous plants succeed everywhere.

In the matter of profit, the districts of Antibes and Cannes rank first; excellent outputs are also secured about the Golfe de Juan and Beaulieu. The total area actually cropped with flowers is nearly 1,800 acres, of which the commune of Nice represents 500, and Cannes, Antibes, Mentone and Grasse each 250 acres. The villa residences commence to encroach on the flower lands, but the house proprietors themselves grow flowers, and that, with letting their villas, helps to make up the means of living. The very large growers of flowers resemble, it may be said, large farmers; they sell their produce to the laboratories or to contractors, or they enter into partnership with intelligent laborers and divide profits. In the winter season the culture is confined to the raising of cut and ornamental flowers. In summer the aim is to cultivate for the laboratories—that is, to distill for perfumery, to prepare essences, pomades and scented "waters"; it is also the season for harvesting seeds.

It is a popular error to suppose that no skill or outlay is required to produce the supplies of flowers for northern latitudes between Christmas and May. Flower culture exacts capital and increasing care. Doubtless many conclude that the flowers grow naturally in the open air—this is an error; some do, but the most delicate and the most beautiful species are raised under glass. In the regions of Nice, Grasse and Mentone there are 200 acres of land covered over with glass frames, each frame costing at least 7s., so that much capital is sunk in the industry. Other flowers are raised under canvas tents, and many are protected by matting. Roses and Pinks are grown under glass; while white Lilac, Lily-of-the-valley, and also Pinks are forced into bloom in the space of eighteen days. The Lilac is white, because grown in darkness, but when exposed to the sun it rapidly assumes its tints, and no fewer than 200 shades of Lilac have been recorded—a collection the late Monsieur Chevreul never could delineate. It is in the bloom and color-producing efficacy of the sun that much of the secret of flower-farming resides. Violets are generally grown beneath the shade of Orange-trees or under the shadow of walls. The Russian variety is classed first, then the Queen Victoria, which is of a deeper hue.

Flower culture could never have succeeded were it not for the railway companies facilitating the industry. They guaranteed the quickest trains from the south to the north of France, accepting the flowers packed in special osier-baskets, and limited to parcel-post weights, never exceeding eleven pounds. It is thus that Nice and other places supply London, Berlin, Stockholm, etc. None go to St. Petersburg; the parcels, even for the imperial family, are too severely handled while passing through the customs. Germany is the best customer of France for flowers. The prices of flowers depend upon the weather and fashion. Formerly Berlin gave the top prices, now all are on a level; while the cultivators have their own daily latest market quotations published the same as for corn, pork or coal. At Cannes, roses range from 2d. to 7s. per dozen; pinks, 1d. to 4s.; Orchids, 1s. 6d. to 3s.; narcissus that sell at one time at 1d. each, can at other times be had at the same price per dozen. Occasionally taste runs in favor of white, red or yellow colors. During the General Boulanger craze in France, and especially Paris, red carnations obtained

fancy prices, because the favorite flower of the then "hero of the day"; of late these flowers do not sell at all.

Flowers for transport are generally cut before sunrise; the best only are chosen, and are packed with cotton, as in the case of camellias, roses and such Orchids as do not stand the journey, or with tissue paper, or even both. Acacia or mimosa generally lines the baskets.

Flowers, as a rule, are not distilled at Grasse, etc., but the leaves, bark, seeds, roots, etc., of odoriferous plants are. The perfume in the other cases is secured by pressing the petals between layers of suet or lard; when the perfume has been absorbed the grease is dissolved in alcohol, which in turn absorbs the essence. Nice and Grasse work up yearly 800 tons of fat and 500 of oil in the preparation of perfumery. It takes twenty-five tons of rose petals to prepare two and a half pounds of essence of roses, the latter representing £100. In 1892 the railway station at Cannes alone forwarded 900 tons of flowers, valued at £160,000. The profits of flower-farming fluctuate between eight and eighteen per cent.

France alone consumes the moiety of the total of her flower output. Paris is the great consumer; the capital needs perfumes and flowers for its fêtes, weddings and funeral ceremonies. It wishes flowers upon mantelpieces above a blazing fire—for bouquets in the eyes of French people mean gayety. A bunch of Parma violets can glide into a muff, can decorate a buttonhole, or ornament a corsage.

The wholesale market of Paris, with which the writer only deals, is held in the central cross alley of the Halles Centrales. In summer—April to September—the hours are 3 to 8 A. M.; in winter, 4 to 9. The right-hand side of the alley is reserved for the flowers from southern France, as delivered by the railway vans; the left side is allocated to the floriculturists of Paris and its suburbs, who have forcing-pits and greenhouses of their own. There are about thirty-two licensed retail sellers, who pay 4d. for their stand of as many hours. There are two sworn auctioneers, who give security each for £400; their fee is five per cent. The thousands of small baskets from Nice, etc., of four to eleven pounds weight, are sold by the dozen; if possible, the same kind of flowers are disposed of simultaneously. Then there is in the distance a regiment of hawkers, who come to buy from the auction salesmen; they have a handcart, which they hire for 6d. a day, paying 2d. more for the liberty to trundle along the streets; these are the subaltern distributors of the floral harvest.

In addition to the special "local" flower markets of Paris, there are 230 fleuristes—there were only forty-five in 1870—or flower-shops, that have magnificent contents along the leading boulevards and main thoroughfares. Their windows are often marvelous displays of floral wealth, united to art. The contents of each window constitute an object-lesson in the harmony of colors, in the arrangement of shades and of volume, of flowering plants [the taste is sometimes questionable, witness the large ribbon bows and satin streamers intermingled]. What wreaths, what bouquets, what painting of the Lily! All is the work of the special lady shop assistant, known as the coloriste; she receives £12 per month for merely dressing the window and inventing combinations for bouquets. The fleuristes in Paris are wealthy, like their customers, who command bouquets and plants varying from £4 to £20. Many of the fleuristes have their own greenhouses in the suburbs, and take by contract what is most beautiful for sale by private growers. They possess every flower "out" of season, of the very newest variety, with the freshest of bloom, and displaying the brightest colors.—*Edward Conner, in The Gardeners' Chronicle.*

## Foreign Correspondence.

### London Letter.

**IRIS ROBINSONIANA.**—English growers of plants for furnishing purposes have been attracted by the elegance of habit and rich green foliage of this Iris, of which a figure was published in GARDEN AND FOREST, vol. iv., 352, prepared from a large specimen which flowered in a sunny greenhouse at Kew. It possesses in an exceptional degree those characters essential to a good furnishing plant, its leaves being far less stiff and better in color than the New Zealand Flax, *Phormium tenax*, which has been tried again and again by market-growers and has always failed to "catch on" with furnishers, owing to its stiffness. The Iris is easily grown in a greenhouse, and as it ripens seeds in abundance a stock of it can be quickly obtained, or it may be propagated by means of division, as it is very prolific of

basal suckers. It will be remembered that this is the "Wedding Flower" of Lord Howe's Island, the home of the Kentias, and that it is by far the largest of all known Irises. It bears tall branching panicles of beautiful white and gold flowers.

**PHÆDRANASSA CHLORACEA.**—When properly treated this is one of the most charming of bulbous plants, and a useful plant for the conservatory. It prefers a sunny greenhouse, a loamy soil, a fair allowance of water while growing and absolute dryness when at rest. The leaves, which are produced with, not after, the flowers, are like those of *Eucharis candida*, but longer in the petiole, and they are covered with a glaucous, almost pale blue bloom, like the bloom of the damson. The flower-scape is erect, eighteen inches high, and it bears an umbel of about a dozen drooping tubular flowers nearly two inches long with acute segments, their color being a beautiful combination of scarlet and blue-green. The plant belongs to the same category as the *Urceolinas* and *Callipsyche*. It is a native of the Peruvian Andes up to 12,000 feet. It is sometimes catalogued by the Dutch bulb dealers, but it is rarely seen in English gardens, although eminently worthy of a place in all good collections.

**DRACÆNA ANGUSTIFOLIA.**—Some young plants of this Malayan species are now attractive in a stove at Kew by reason of their large arching branched panicles of white flowers, which are sufficiently attractive to place this species among flowering stove plants, an unusual character in the genus. The Kew plants have erect, unbranched stems eighteen inches high and a quarter of an inch thick, leafy to the base, the leaves bright green, narrow, a foot long. The panicle of flowers springs from the top of the plant and is two feet long, branched, the branches nine inches long, the whole clothed with narrow tubular flowers nearly an inch long. According to the description of this species in Hooker's *Flora of British India*, it forms a stem eight to ten feet high, as thick as a stout cane, simple or forked, the leaves sometimes twenty inches long, the panicle very large, the flowers white or tipped with pink, and the fruit half an inch in diameter, fleshy and orange-colored. It is a true *Dracæna*, not a *Cordyline*, and is a native of Australia as well as India.

**CROTALARIA LONGIROSTRATA.**—We obtained this plant from seeds sent to Kew by Mr. J. N. Rose, of the United States Department of Agriculture, in 1891. It is now one of the most useful of shrubby legumes grown in pots for the decoration of the greenhouse in winter and spring. Cuttings are struck annually in a stove and the plants are grown in a sunny frame all summer along with *Poinsettias*. They form shapely little shrubs about two feet high, with pinnate leaves of a soft green color, and long-stalked, erect racemes of bright yellow flowers about the size of those of the common Laburnum. Planted in a bed out-of-doors in June a batch of plants made healthy growth, but did not flower. In subtropical climates where the atmosphere is fairly dry it would probably prove a first-rate shrub for the open. Of the several hundreds of *Crotalarias* known very few are of any value as decorative plants. *C. juncea*, the Sunn-Hemp, sometimes develops with us into a presentable shrub, and its golden-yellow flowers are decidedly ornamental.

**COLUMNÆA SCHIEDEANA.**—This is a large-flowered, attractive stove-plant two or three feet high, with fleshy stems, lanceolate dark green leaves four inches long, and axillary clusters of stalked, tubular, two-lipped flowers three inches long and colored dull crimson and brown, the conspicuous calyx being bright red. It is easily grown, requiring similar treatment to shrubby *Begonias*, and it flowers freely in February and March. The genus is a near ally of *Alloplectus* and *Drymonia*, and it is said to contain about sixty species, all natives of the tropics of the New World. Only very few, however, of them have ever been introduced, and perhaps not more than three or four are in cultivation now. One of the most striking is the Colombian *Columnæa Kalbreyeriana*, with a short stem, large leaves and clusters of bright yellow flowers. *C. Schiedeana* was introduced

from Mexico many years ago, and was figured in *The Botanical Magazine*, t. 4045. It is cultivated in continental gardens under the name of *C. erythrophæa*.

*DIDYMOCARPUS HUMBOLDTIANA*.—This is a tropical representative of the Pyrenean *Ramondia*. It is, therefore, too small to find general favor among cultivators of showy things only; nevertheless it deserves a place among choice tropical plants. It is by far the most tractable under arti-

branched peduncles rise to a height of three or four inches and bear numerous broad-tubed *Gloxinia*-shaped flowers nearly an inch long and colored pale purple in the type, white, with a blotch of yellow in the variety *alba*. It has been flowering since last autumn, and is now ripening seeds. It is a native of Ceylon. There are about seventy species known, all natives of tropical Asia.

*PRIMULA OBCONICA ROSEA*.—This is a considerable improve-

Fig. 15.—The Cypress-tree of Tule.—See page 123.

ficial treatment of all the species of *Didymocarpus* that I have tried (*D. Malayana*, Messrs. Veitch's recent introduction, I only know from experience with small seedlings up to the present), for it grows and keeps healthy when kept on a shelf in a warm house and treated the same as *Gloxinias*. It has broadly elliptic, wrinkled, hairy leaves three inches long, which lie flat on the ground, *Ramondia*-like, forming a tuft, from the centre of which the slender,

ment upon the type, both in regard to the size and color of its flowers. Messrs. Ware, of Tottenham, exhibited a batch of it in flower at the last meeting of the Royal Horticultural Society, from whom it received a certificate. It has large, well-formed trusses of flowers, each an inch across and colored clear rosy pink. Along with it were well-grown examples of the type and of the variety *grandiflora*, the flowers of which are pale lilac, almost white in fact,

when developed in a little heat. Ever since its introduction from China in 1882 cultivators have been striving to cross this species with other good garden sorts without any definite result having ever been obtained, but it appears likely that variety, in both size and color of flowers, is being gradually evolved solely by high cultivation and selection. There is, for instance, a marked difference between the best forms of this species as now known and the type as represented in *The Botanical Magazine*, t. 6582.

**CYCLAMEN PERSICUM** AGAIN.—Two additional sports have been recorded this week, namely, an exceptionally large-flowered pure white form, named *Grandiflorum album*, the petals being broad and measuring nearly three inches in length. It was shown in magnificent condition by the St. George's Nursery Company, Hanwell, and was awarded a certificate by the Royal Horticultural Society. The second is a red-flowered variety of the sport with crested petals which originated in a garden in France three years ago, and is reproduced from seeds. It will be remembered that Messrs. Low & Co. have raised a white-flowered variety with crested petals, and this also comes true from seeds. Dr. Masters suggests that these sports are due to hypertrophy or overgrowth, caused by excessive feeding, and that they may be looked upon as a "variation formed as it were beneath our eyes, and one, moreover, which in so far resembles a species that its characteristics are reproduced from seed."

London.

W. Watson.

### Plant Notes.

**IRIS ROSENBACHIANA**.—Some mild day in March, or even in late February, if genial conditions prevail, there will be seen rising from the bare earth a short cluster of leaves about the size of a finger-tip. Very shortly after, this Bokharan Iris will expand its fair, not to say gaudy, flowers, fully unrolling in a few hours after it shows color. In the early year flowers are either short-stemmed or sessile, as if they feared to trust themselves too freely to Nature's buffetings. It is only as the season advances that the leaves and peduncles expand to produce bolder effects in the garden. Even the bold Daffodils send the smallest and daintiest of the race as a courier, and *Narcissus minimus*, which now appears as usual, is scarcely as large as a Snowdrop. The early Irises have but small flowers and show not much foliage, and this is linear. The best forms of the *Reticulata* section are modest in size as well as color, *I. histrioides* being the most prominent for mere inches. Much more showy than any of these, though little exceeding them in size, is *I. rosenbachiana*, which begins to show itself before the smaller Irises have passed. This has an ovoid bulb with short perennial (or perhaps persistent) roots very much thickened where they join the bulb. Botanically it is of the *Juno* section, one of the most striking of its characteristics being the very small standards, which are a perfect antithesis to the bold standards of the German Irises. The flowers have very long tubes, long narrow styles, still narrower claws and a short vividly colored fall. They are said to vary materially in coloring, from white to shades of purple. Those in my garden are light purple, shading to white, except on the falls, which are a rich reddish purple. The flower has a bright orange ridge, bordered to the base of the claw with distinct narrow lines of purple. Away from its surroundings it appears only as a pretty thing, but rising from the bare earth with no foil of foliage under the conditions prevailing in March, it is distinctly gaudy and one of the oddest productions of nature. It is a much taller flower than that of the better-known *I. persica* (also of the *Juno* section), whose coloring is rather of a livid hue, though it always appears to one as a surprising flower. It may be added that *I. rosenbachiana* usually has two, and sometimes three, flowers in succession, bears seeds in this climate, and seems fairly thrifty when planted in moderately light soil, where the bulbs are dry in summer. It has not increased in the three

or four years in which it has grown and flowered here, but it has never failed to flower, and has not degenerated, as summer-resting bulbs often do. Slowness of increase is often more the fault of the gardener than the plant.

Elizabeth, N. J.

J. N. Gerard.

## Cultural Department.

### Erythroniums.

**M**R. PURDY, on page 106, speaks none too highly of these beautiful flowers, which are among the daintiest and most graceful of the early season. The cultural directions, so carefully detailed, are very interesting and valuable, and any further comment would seem uncalled for had not Mr. Purdy rather discouraged careless growers or those who are not inclined to take special pains with their plants. Eastern growers do not need any special warning against native California plants, which have a reputation, not wholly undeserved, of being, as a rule, rather difficult subjects to retain in the garden from the fact that they begin to grow too early and that it is difficult to give them their natural rest. However, they are mostly amenable to rational treatment, and most of them fully repay any care required. But my experience with a few bulbs each of half a dozen species of *Erythroniums* which I had from Mr. Purdy three or four years ago, does not bear out the doubt expressed as to their success under other conditions than those noted. My bulbs are planted in the stiffest of clay soils in a border which has had no cultivation to speak of, and certainly no manure or humus for over a decade. They are in the wettest spot in the garden, where water stands if anywhere, yet the bulbs have always flowered, and I notice that they are again showing buds. I doubt if they have increased in numbers, but this does not seem surprising under the circumstances, and I do not know that they naturally increase as fast as our local Dog-tooth Violets, which devote themselves so much to vegetative growth that one cannot in some seasons find a flower on a thousand plants. If they have the same extraordinary underground growth as our eastern *Erythronium*, which, by its lengthening stolons, plants new buds generously in every direction and at all depths, perhaps culture in stiff soil may act as a repression to increase of growth, but be helpful to number of flowers.

These two experiences are only an illustration of the fact that many plants have a great range of adaptability to varying conditions, and that in the garden one may have success with the same plants under widely different cultures. Gardening is very empirical, and cannot be confined to rigid rules. No garden is a true home for all plants, and no grower succeeds with all; in fact, the specialist of a few species is apt to find that as soon as "he knows it all" this is a pride which cometh before a fall, and that any plant may be as capricious as, say, the gentler sex, and more interesting in either case because capricious.

Elizabeth, N. J.

J. N. Gerard.

### Fancy-leaved Caladiums.

**T**HE tubers of these plants which are intended for the decoration of the greenhouse during summer should now be started into active growth, while those which are to be cut up to multiply any desirable sort should be selected, labeled and kept in dry sand till a little later in the season. Tubers best suited for the latter purpose are the ones which show signs of starting around the sides, while for growing into plants with large leaves in a reasonably short period, those of a fairly large size without side growths are preferred. To save space for a few weeks the tubers can be started rather closely together in shallow boxes or on benches, with finely chopped moss or rough sand as a cover; but this method, although it saves space, has its drawbacks. The tubers do not all break into growth at one time, some of them being almost in a dormant state, while others are ready to be put in pots; again, the roots are apt to get mutilated in the transfer, which causes a serious check to many of the finer kinds. I prefer to use small pots for starting the tubers, as it is a very much more satisfactory method. Three and four inch pots will be found large enough for the purpose; where three-inch is too large, then two or more small tubers of a kind may be put together.

To grow a plant successfully a great deal depends upon securing thick healthy roots at the start. These roots are produced at the top of the tuber just at the base of the growing leaf-shoot, so that the tubers should be planted deep enough to insure good rooting conditions on the top instead of at the bottom. I find the best potting material for starting tubers to

be of chopped sphagnum moss and well-decayed cow manure in equal proportions; the manure should be put through a No. 4 sieve and the moss through a No. 2. Add a liberal sprinkling of sharp sand, press this material pretty tightly around the tuber and leave a space of at least one inch below the rims of the pots; to keep them in a uniformly moist state a layer of moss can be placed between the pots when standing them on the bench. When they have grown sufficiently for their first shift, some of these high-colored, slow-growing kinds which have recently been sent out will do all the better if a similar compost is used in this operation, but care ought to be taken to have the pots sufficiently drained and the compost firmly pressed. Grown this way they need more water than when grown in soil.

Botanic Garden, Washington, D. C.

G. W. Oliver.

### Nelumbiums and Hardy Nymphæas.

THE Egyptian Lotus has gained such an established reputation in this country that every lover of aquatic plants who has any place to grow them aims to have them. Although these plants are perfectly hardy they are rather difficult to establish. This is a good time to plant hardy Nymphæas, and although Nelumbiums are also hardy they should not be treated the same. Most of the Nelumbiums are indigenous to warmer climates than the hardy Nymphæas are, and are more impatient of removal. Many failures have resulted from digging tubers and transplanting them too early in the season, and as seasons vary considerably what is applicable in one state may be fatal in another state, or even in another section of the same state. Some general conditions exist, however, in all parts of the country, but the date of these varies with the latitude. In the southern counties of New Jersey bordering on the Atlantic and on Delaware Bay vegetation is three to four weeks earlier than in the northern part of the state. A similar difference exists in other states, so that the precise time for planting must be judged locally. But it may be considered safe to plant Nelumbiums when there are indications of spring weather, that is, when the early-flowering shrubs, such as the Forsythia, Japan Quince, Wild Cherry, etc., put forth their blossoms, when the grass is not only green, but ready for the mower, and the Dandelions are gleaming on the lawn. These are not harbingers of spring, but declare clearly that spring is here.

In some sections of the country where Nelumbiums are established they have penetrated into deep soil and some are in deep water. These are slow in starting into growth in spring, for it takes a long time for a large body of water to become warmed by the rays of the sun, and consequently the tubers remain in a dormant state for a longer time. Artificial ponds should, therefore, not be too deep, but deep enough to protect the tubers from freezing. Two feet of ice above them will do no injury so long as the tubers themselves are not frozen. In spring the water may be drawn off and a few inches will suffice. When planting or transplanting in spring, dormant tubers, or those already active, are sure to grow under the weather conditions referred to, but if planted while it is cold—and a cold spell often follows the few first warm days of spring—when the tubers have already become excited or started to grow, the check to their growth consequent on the chill will, undoubtedly, prove fatal. In planting Nelumbiums it is well to make haste slowly.

There are numerous varieties of Nelumbiums. The well-known Egyptian, so called; the Chinese; the Japanese of various hues and shades of color, from pure white to deep carmine, single and double; and the native American Lotus, *Nelumbo lutea*. The latter is not as vigorous in this section as the others and is consequently more difficult to establish. The best treatment is to start the tubers indoors in seed-pans or pots, or even in an old pail, and when well established to transplant in permanent quarters. Seed may also be started and grown on in pots and afterward transferred to tubs or planted in ponds, but the seedlings will not flower the first season. Among those of recent introduction a few deserve to be better known and more generally grown. *Album striatum* is robust, vigorous and free-flowering. The flowers are large, pure white, flaked and margined with crimson-carmine; sometimes this coloring is slight, and at a short distance the flowers appear pure white. They have exquisite fragrance. *Kermesina* is not so robust, but is vigorous and free-flowering and equals *N. speciosa*. The flower is a delicate shade of carmine-rose. *N. rosea* is also of good constitution. The flower is bold and massive and the deepest rose-color of any in cultivation.

Hardy Nymphæas may be planted two or three weeks ahead

of Nelumbiums and should receive attention first. Yet these may be planted any time during summer, and as late as the first of September in warm sections. The season for flowers will be short, however, if there are any flowers at all, but an advantage is gained for the following season. The great improvement of varieties and the addition of new ones make them highly valuable as hardy decorative plants. Only a few years ago a hardy pink variety was a valuable novelty and limited in distribution; but now this class embraces all the deep rich reds of the tropical varieties, and in some instances they are unsurpassed. The blending of colors in these charming flowers baffles description. Among those within reach of most cultivators and deserving of mention are *Nymphæa Marliacea carnea*, *N. Marliacea rosea*, *N. Laydekeri rosea*, *N. Laydekeri purpurea* and *N. lilacea*. Among those that are yet scarce, and consequently high in price, are such superb varieties as *N. Robinsoni*, *N. lucida*, *N. flammea*, *N. ignea* and *N. fulgens*. These are fiery crimson, orange-scarlet and purplish maroon, with intermediate shades unsurpassed by any other class of hardy plants.

Riverton, N. J.

W. Tricker.

### Soils and Potting.

AT a recent meeting of the Massachusetts Horticultural Society, Mr. T. D. Hatfield read a paper on the above title, and we quote from an abstract of it which appeared in the *Evening Transcript*, of Boston:

Gardeners seldom agree entirely about the proper soil for any crop. Soil may be heavy or light, the land high or low and with much variation of exposure, and we often wonder at our neighbor's success under conditions where we should consider failure certain. An acquaintance of mine, a gardener at Cape Ann, told me that the only potting soil he could find was turf from what had once been a salt marsh. After it had been broken up and exposed to frost and air he found he could grow almost anything in it.

We gardeners believe in "leaving well enough alone," and there are methods which we continue because it is the custom, though we cannot explain why. We read in old books, "one-third turfy loam, one-third leaf-soil and one-third sand," or it may be fourths, including rotted manure, or four-fifths, with peat added. This accurate measuring, however, is slow, and but few such mixtures of soil are in use to-day by men who have left off obeying the rule of thumb and have taken lessons in the school of experience. Leaf-soil, one of the best ingredients in any compost, is seldom used except in private gardens. Well-rotted manure is a good substitute. However, the soil should be light for potted plants and there is less danger from overwatering with the hose. Rose-growers always find means of meeting the wants of the soil. They may add clay, but can generally do without it.

With Azaleas it used to be considered necessary to use English peat, and ninety per cent. of these plants are still so grown in England. But look at the Azaleas grown by Mr. Sander, gardener to Professor Sargent, of Brookline, and you will see that Azaleas can be grown in soil almost wholly lacking peat.

There are other considerations almost as important as the soil and its consistency. For Gloxinias I tried various kinds of soil to little advantage. With these plants much depends on caring for the tubers during the so-called resting season, though they are never absolutely at rest, and it is a mistake to remove them and store in dry sand. They should never become thoroughly dry, for living shoots will always be found which require some nourishment. Start with sound, healthy roots, withholding water until some leaf-growth is made, and keep them near the light, and then Gloxinias will succeed in almost any soil.

I have but one compost heap. Good turfy loam is not plentiful, and some of us have found how to get along without it. Old Country Carnation growers are extremely carefully in mixing their potting soil, but the American grower prepares his in the field without a foot of turf. The best method is to cultivate the area for stripping, growing thereon a crop of clover with no other object beyond turning the best of what is put into the soil as manure into plant-food of the kind which the Carnation most needs. The American grower raises the better Carnations, though it is true he has better light during winter-time, has made a specialty of the work, and has originated a new type of the plant. This shows that the importance of a prescribed composition for soil is overestimated. I have grown Chrysanthemums in soil from the common compost heap which were just as good as those grown in special soil.

In the spring there is generally turf trimming to be done, and I used to get enough in this way for a season's use; but

now if I get a half-dozen cartloads of turf I mix it with two loads of the best manure—sheep-manure is preferred, as it is richer, so that less is required. This I put in layers alternately with pure ground bone; fermentation starts and the soil is heated to 120 degrees, Fahrenheit, which will kill all insect-life and weed seeds and make the bone meal available as plant-food. Bone meal should be worked into the compost long before it is needed, as it is not fit for use until fermentation has subsided. It should never be used as a top-dressing. I have said that light soil is best for potted plants, but a man may get along with heavy soil if he understands its management. Injudicious watering will lessen the value of the best compost, and lack of air and of proper heat and moisture would ruin the best plants.

In potting plants clean pots are a necessity. If new, expose them to a rainstorm, or else fill with moist earth and leave for a day or two to deodorize them. This earth should not be used again. Next in importance is good drainage. The best material is crocks of broken pots. Coal ashes, though excellent for many plants, is bad for others. Plants which do the greater part of their growing in winter-time, as well as those which remain a long time without repotting, require most care. All potting should be done firmly and for the most part by hand. Plants which grow quickly, Geraniums, Heliotropes, Coleus and Fuchsias—what gardeners call soft-wooded plants—need less care. Amateurs often put out their window-plants for a summer's growth, and it is pleasant to see how luxuriantly they grow with unrestricted root area, fresh air and sunshine. But in winter again they must be pruned and curtailed in root-room. Geraniums and almost all window-plants stand this rough treatment. I, myself, should prefer to dispense with old plants, having raised a lot of young stock in the mean time.

Amateurs often ask what fertilizers to use for potted plants, when all that is needed is better light and air, or more or less heat. The best of liquid manures for potted plants, to continue the productiveness of flowers or fruits after the natural resources of the soil have been exhausted, is the dregs from the barnyard. It is well to start with one-eighth strength and increase as experience dictates. Colorado sheep-manure may be used at the rate of a peck to fifty gallons of water. Sulphate of ammonia and nitrate of soda, at the rate of one pound to fifty gallons, furnish nitrogen in a form easily assimilated, and their action is quick of benefit as well as of injury. These should only be given in such quantities as the plant can digest. Even if a surplus did no injury to the plants it soon leaches away and is lost. Liquid manures should be used only on healthy plants, and free drainage must be secured at all hazards.

#### Azalea Indica.

MOST of the varieties of Indian Azaleas which are generally brought into flower for Easter are now beginning to show their colors. It is usually somewhat difficult to keep them back until this time even in the coolest possible quarters, but this year they seem to be developing so as to be at their best at the right time. The weather, which until recently has been somewhat dull and sunless, has doubtless had a retarding influence. The most forward of all the varieties is the pure white *Deutsche Perle*, which is generally the first to flower. The buds on *A. Indica alba* are also well forward, and while this old favorite is less popular than the newer sorts, it has not yet been excelled for freedom of growth and flower, and we still value it as a useful variety for cutting. *Apollo* is another good white variety of the older sorts, and its flowers are among the largest. *Louisa Pynaert* is also white, and unrivaled in purity and substance, but somewhat shy in flowering. *Imbricata*, a white variety flaked with rose, on the contrary, is more inclined to make flowers than growth. Other good varieties, old and new, are *A. Borsig*, *Ami du Cœur*, *Bernhard Andre* and its white variety, *alba*, the double-flowered *Camellie*, *Candidissima*, *Flambeau*, *Madame Camille Van Langenhove*, *Madame Iris Lefebvre*, *Madame Van Houtte*, *Pharilde Mathilde*, *President Oswald De Kerchove*, *Princess Alice*, *Theodore Riemers*, *Stella* and *Vervaeneana*. These varieties are very numerous, and these are only a few of the best of those with which I have familiar acquaintance.

One of the points of cultivation which should be attended to now is the pinching out of all young growths as they appear alongside the flower-buds. If these are allowed to grow, the flowers will be quite worthless. They appear on most plants at this time, no matter how carefully they may have been cultivated. They are often induced by feeding after the buds are set. This is a mistake and should be avoided, though fre-

quent applications of weak liquid-manure may be given while the plants are in active growth; the inducement of soft growth must be guarded against. Syringing is important in maintaining the vigor of the foliage, and it also helps to keep in check such troublesome insects as thrips and red spider.

We find that planting out after the beginning of June is the simplest and most convenient method of summer cultivation, unless for large plants. A liberal supply of leaf-mold should be worked into the soil where they are to be placed. Watering is, of course, necessary during dry weather, but it is easy to maintain an even moisture about the roots of the plants under this treatment as compared with the former practice of plunging the pots. We like to see the buds well set before lifting in fall, but it is better to lift a little early rather than incur danger from freezing.

### Is the White Pine Doomed?

To the Editor of GARDEN AND FOREST:

Sir,—I have read with interest the very ingenious and highly philosophical, yet rather unnecessarily forced and, I believe, erroneous explanation which Professor Corbett advances in your issue of March 24th for the difficulty which the White Pine seems to experience in reproducing itself, namely, because, with the Coniferæ in general, the Pines are "less highly organized" morphologically, they are "less virile than many of their competitors," and "more congenial conditions for growth and development must be provided for them than for other species with which they now have to contend." And finally he states that "the White Pine requires extra care to induce it to perpetuate itself." These statements might be misconstrued into meaning that the Pines are more fastidious than other species regarding conditions of successful reproduction. This would be a grave mistake, for, on the contrary, the Pines, of all trees, are among the most frugal, able to exist, and even thrive, in the poorest and driest soils and climates, where no other trees will. Is it not the tree of trees for sand dunes? Does not *Pinus rigida* maintain itself in the most forbidding gravels and sands of the Jersey plain? Is not *P. Virginiana* the very emblem of frugality? Does not *P. Tæda* immediately take possession of the abandoned southern fields, keeping out all competitors and wrestling even in the swamp for supremacy? Do not *P. edulis* and *P. ponderosa* occupy the driest slopes and exposures of the Rockies, and does not the latter range from arid southern Arizona to humid British Columbia, showing a most remarkable adaptability which few species share? Is not *P. Banksiana* the most frugal inhabitant of the northern Pine lands, and does not *P. resinosa* thrive in the swamps of Minnesota as readily as in the dry gravels, showing hardly any difference in the rate of growth? And the White Pine is no exception to the rule—nay, if anything, it is even more adaptive in certain directions.

Within its climatic range and even beyond its natural limits of distribution it occupies, or may be made to occupy, the greatest variety of soils, and may be propagated with the greatest ease. That there is no more difficulty than with most other species in regard to its spontaneous reproduction, if the chances are even, may be seen in the hill country of Massachusetts, as well as in the true Pine country of Wisconsin and Minnesota. Wherever an opening large enough is made young seedlings quickly appear and find no difficulty in maintaining themselves against broad-leaved competitors, if only the fire did not come to the aid of the latter. For these have one advantage in their constitution over the Pine and one only, namely, that they can sprout from the burnt stump. As to their seeds, contrary to Mr. Corbett's supposition, it is well known that those of the Pine retain their germinative power much longer than many and as long as most broad-leaved species. To be sure, the observed deficiency in the recuperation of the White Pine growths is, as Professor Corbett suggests, due to unfavorable conditions, but these are entirely extraneous and not inherent in the constitution of the Pine or its seed. Any other species treated in the same way would and does react similarly. Even the White Oak, most tenacious of life, can be almost exterminated, as some parts of Kentucky testify. Cull out all or most of the old White Oak in a mixed forest, leaving all other species to shade the ground and to compete in much larger number for the openings and you will soon miss all reproduction of that light-needing species. Thus, it is the culling of the Pine, reducing their number as compared with its competitors, and the leaving of these to

shade the ground, which reduces its chance for reproduction in spite of its considerable shade endurance.

Not special care, but merely giving an even chance for reproduction, is needed to recuperate the White Pine. To be sure, being our most useful timber, it deserves to be given even a better chance by removing such of its competitors as are less useful.

That the explanation of the rotation of forest crops lies mainly in the relative shade endurance of the species and the variation in light conditions produced either by the action of man or of nature, is too well established to require any other explanation.

Washington, D. C.

B. E. Fernow.

### The New Forest Reserves.

To the Editor of GARDEN AND FOREST:

Sir,—Will you allow an Englishman, who has seen with his own eyes in many western states the frightful devastation of the most magnificent heritage of the American people, to congratulate you, as editor of GARDEN AND FOREST, on the success of your patriotic and wise efforts, continued for many years, to preserve some part of those unrivaled forests in a state of nature. I do not think that any act of the late Presidents will have such good and lasting results as this, if effectual measures are taken to protect the new reserves from fire, grazing and the reckless slaughter of game, which has been so detrimental to them.

I cannot help thinking that until a permanent staff of competent forest officers can be trained and appointed you will find that detachments of the regular army under selected officers will prove the most effective and honest guardians of the reserves, and though the areas defined are small enough in comparison with the vast areas which are already either wholly or partially ruined, yet the step just taken is one which goes beyond what could have been expected at the present moment. There still remain, however, some regions in which similar reserves seem to be almost as much wanted. Among them I might mention a district in north-western Colorado, and another in western North Carolina. It may be too late, but, as an illustration of what we are reduced to here, I may say that our Government is at last obliged to purchase a large tract of land on Salisbury Plain simply because there was no area of open land in southern England large enough for military manoeuvres.

Colesborne, England.

H. T. Elwes.

### Exhibitions.

#### Spring Flower Show at Boston.

ALL the visitors at the exhibition of the Massachusetts Horticultural Society last week agreed that this was, upon the whole, rather better than any spring show yet held by the society, one reason being that such fine weather prevailed at the time of opening that exhibitors had no fear that their plants would be injured by the cold, and therefore they took the best they had. The classes were usually well filled, although there were no competitors for the group of Orchids covering forty square feet. It is rather odd that in the schedule of prizes a date should have been selected for the largest premium on these plants just between the season of their winter and summer bloom. The great masses of Cyclamens, Cinerarias and the varied exhibition of forced bulbs were the leading features of the show as a popular spectacle. The shrubs in flower were also good, although the Indian Azaleas were not up to the highest standard of excellence. There were a few other hard-wooded plants in flower, good Acacias, Epacris, etc., but none of great interest, except from a cultural point of view. There never was so fine a competition of Carnations at a spring show, and the hundred blooms of no less than six varieties, with their foliage, for which William Nicholson took first prize, were exceptionally good, and so were the vases of Ferdinand Margold, William Scott, Daybreak, Hector and Eldorado, with which Mr. Nicholson took first prize for the best five flowers of a crimson, a dark pink, a light pink, a scarlet and a yellow variety. A new white flower called Freedom, shown by Peter Fisher, was a fine flower, and so was the Nivea of H. A. Cook. The Cyclamens were far in advance of anything previously seen in Boston, and by the great mass of visitors were considered the most interesting of the plant exhibits. There were some fifty plants in twelve-inch pots which took the first prize in various classes grown by John Barr, gardener to Mrs. B. P. Cheney. They were superb examples of culture. The bulbous plants were unusually numerous, conspicuous among which were the Trumpet Narcissus, Tulips and Jonquils of Elwell & Son. In

the fine display of cut flowers of hybrid Roses one shown by David Nevins, called La Rosiere, was as perfect in its color (crimson) as Prince Camille de Rohan, but of better form and fragrance, and it adds another one to the very short list of common Roses which can be satisfactorily forced. Other conspicuous Roses were those of American Beauty, Meteor and Souvenir de President Carnot, for which F. R. Pierson received the first award, besides Bridesmaid and Bride, with which W. H. Elliott took the same rank. A finely flowered specimen of the Crimson Rambler Rose was in the large display of forced shrubs from the Bussey Institution, which included Daphne Cneorum, Lilacs, Kalmias and the like. Noteworthy specimen shrubs were John L. Gardner's fragrant Boronia megastigma and Dr. Weld's Acacia Drummondii, Boronia elatior and Erica Cavendishii. The cut flowers of Camellias from Mr. Joseph H. White were much admired, and they took the mind back to the time when a display of these flowers was indispensable to every spring exhibition. There were about a hundred flowers exhibited, each one with a spray of its own foliage. A cut spray of the double-flowering Japanese Cherry, exhibited by James Comley, was exceedingly beautiful, and received a silver medal from the society. It seemed to be a form of Prunus Pseudo-cerasus, but it differs from any now known in cultivation.

Besides the prize-takers already named, the chief awards for plants were made to Dr. C. G. Weld, the Bussey Institution, Jackson Dawson (for Crimson Rambler), John L. Gardner, James L. Little and J. W. Howard. There was an interesting display of fruits and vegetables, and Jackson Dawson received a special award for some well-fruited Strawberry-plants.

### Notes.

Winter beets, turnips, cabbage, carrots and onions are gradually giving place to the new crops of these vegetables from the southern states, Bermuda and the West Indies. Eggplants are coming in considerable quantity from Florida and Cuba, and lettuce from the southern Atlantic coast states. Spinach and kale, from Virginia, are plentiful and cheap. The best out-of-door tomatoes come from Florida, those from Key West being rather inferior in quality. Heavy stalks of Colossal asparagus in full-sized bunches, from North and South Carolina, sell for fifty cents. No cucumbers have come from Florida since the heavy frost there in January until now, when a few crates are being forwarded. Celery finds ready sale, and a choice is afforded in the varying kinds from Florida, California and the interior of this state. Peas and string-beans, some of choice and others of indifferent quality, still come from Florida, the best being hurried northward by express, while the cheaper grades come by freight. One of the most costly field vegetables now in market is Bermuda potatoes; large ones of the new crop cost \$9 00 a barrel at wholesale.

Mr. Robert Simpson, writing to *The American Florist*, says that it is a mistake to feed Roses under glass or other plants of this class abundantly in autumn or early winter, while the plants are small and soft and while the soil is still rich in plant-food, with comparatively few roots to use it. But in the spring, when the soil is full of roots, the sun powerful and the growth rapid, unless nutriment is furnished just as fast as it can be consumed by the plants, small shoots and smaller flowers will be the result. Of course, we cannot take fresh manure from the stable into the greenhouse and use it as a mulch. It should have been heaped up last summer, turned over once or twice in the autumn, and stored before cold weather in a shed or other dry place where it can be reached and handled at any time. In this season of growth the surface of the benches should be sprinkled over with a dusting of finely ground bone or wood ashes, or, better still, with a mixture of both, and this should be covered with a mulch an inch thick of the well-rotted manure and soil mixed in equal quantities. Liquid manure may be omitted for a week after the mulch is spread, otherwise it should be attended to faithfully and regularly, giving it frequently in a very diluted form.

A serious cane-blight of the Currant, which has been attributed to poor soil and hard winters, is really the work of a fungus which is described in Bulletin 125 of the Cornell University Station. The first effect of the disease is seen in wilted foliage and premature coloring of the fruits. Then the leaves dry up and fall away, the berries shrivel and fall, and the bare canes die rapidly. Sometimes the plants die before the leaves unfold, so that unopened buds are seen on the dead branches, and in the worst cases the roots die with the canes. Without giving any detailed description of this fungus, to which allusion has already been made in these

pages, it is enough to say that the mycelium having once gained entrance to a plant may live there for a long time and be transmitted with the cuttings. Cuttings should therefore be taken from plants known to be free from disease, and it is not safe to take them from absolutely healthy plants in the neighborhood of diseased ones. They ought to be obtained from localities where the disease is not present. The best remedy is the removal of the entire plant as soon as the disease begins to be manifest. It should then be burned, because the spores and conidia may be produced on dead plants, and the trouble in this way communicated to the living bushes.

*Adonis vernalis* is well known as a hardy plant both for the garden border and for rock-work, and if left without frequent transplanting often it soon becomes established and its large yellow corolla, seen above the deeply cut leaves, makes a beautiful show in early spring. *The Gardeners' Magazine* gives an illustration of another species of this genus, *Adonis Amurensis*, which certainly looks as if it would be a worthy companion of the better-known plant. The picture was taken from a specimen in the rock-garden at Kew, where the plant occupies a shaded nook and was blooming at its best about the middle of February. Mr. Watson spoke of it about a year ago in this journal as flowering for the first time in Europe although it has long been known in the east, and no less than twenty-one colored figures, representing distinct garden varieties of it, are published in one Japanese work. There are double and single flowered varieties, some yellow, others orange, others bright red. As they would probably be hardy in this country they might make useful additions to our early-flowering herbaceous plants. This species was discovered in the Amur Provinces of Russia, and it has also been found in the north of Nippon.

*The Rural New-Yorker*, in reply to the inquiry whether Strawberries should be cultivated in the spring before they fruit, received answers which show that practice in this regard varies widely among experts. Some growers say that one acre when cultivated in the spring will yield as much as two neglected ones, while others feel that it is the wisest practice to leave the mulch between the rows and never touch the ground with the hoe until after the fruit has been gathered. The facts seem to be that during the spring and summer after the plants have been transplanted the roots grow downward to get away from the heated surface to find water. When cool autumn weather comes, fine feeding roots take possession of the surface of the soil and these are the ones upon which the spring growth of the plant depends and which mature the fruit. Of course, hoeing the ground in the spring will kill these roots and reduce the fruiting power of the plants. But after the fruiting season the old roots are useless and the plant begins to send out new ones which again reach downward, and this is the time for cultivating on the surface. In the cool of autumn a second crop of roots takes possession of the surface soil, and if the mulch is left on the ground the next spring these will be the most valuable working roots. Perhaps the men who succeed with spring cultivation are those who keep up rather deep cultivation late in the fall which compels the roots to run deep. In this case the hoe in the spring will find no roots to injure and cultivation does good. Of course, nothing but the surface is hoed, and after the hoeing is done a mulch is laid over the surface and new roots will quickly run through this upper layer to provide food for the growing crop.

Among specialties in the fruit-stores this week is guavapaste from Venezuela, a dry marmalade of agreeable flavor with appetizing qualities, and easily kept and handled, as it comes in square bars wrapped in paper. Packages of one pound cost twenty-five cents, and five pounds are offered for seventy-five cents. Sapodillos, in edible condition, cost sixty cents a dozen. The first mangoes of the season have arrived in a private consignment from the West Indies, and this fruit will soon be regularly in the trade. Large irregular-shaped yams bring twenty-five cents for three pounds. Preserved bananas, a novelty in this market, are seen in a down-town fruit-store. They are entire, peeled, with the flavor of the fresh fruit, brown in color, somewhat toughened in evaporation, and are packed in layers in boxes, to be eaten out of hand. They cost twenty cents a pound. Florida Navel oranges of large size sell for fifty to seventy-five cents a dozen, and the kind known as Jaffa Seedless, with only occasional seeds, and also from Florida, bring an equal price. Grape-fruit from the same state commands \$5.00 a dozen, or fifty cents apiece for large selected specimens. The quantity of Blood oranges seen this season is uncommonly large; this showy fruit comes from Messina and from California. That from the western coast costs fifty

to sixty cents a dozen for the best, or a third more than the Italian fruit; it is more highly colored than that from Europe, has a more pronounced flavor, and is somewhat more acid than the seedling oranges from California. Almeria grapes, carried over in refrigerators, sell at thirty to fifty cents, and foreign hot-house grapes for \$2.50 and \$3.00 a pound with the end of the season in view, though hot-house grapes from Rhode Island will quickly follow the imported ones. California honey, at fifty cents for a quart jar, black currant jam and jelly and three-pound jars of preserved cherries, pineapples and peaches, carefully prepared by private establishments in this city, are among the wholesome delicacies seen in the stock of fruiterers.

Charles Eliot, of the firm of Olmsted, Olmsted & Eliot, died suddenly at his home in Brookline, Massachusetts, on Thursday, the 25th of March, in the thirty-eighth year of his age. He was the son of President Eliot, of Harvard University, from which he graduated in 1882, taking afterward a special horticultural course in the Bussey Institute to prepare himself for the profession of landscape-gardening. After traveling in Europe and studying the best examples of landscape-art in Great Britain and on the Continent he entered the office of Frederick Law Olmsted, with whose love of nature and artistic ideas he was in such full sympathy that he was soon entrusted with the design of works of considerable importance. At the conclusion of his studies he established himself in practice in Boston, where he achieved the success which a self-reliant, though unobtrusive, young man of original faculty and careful training had reason to expect. His greatest public service, however, at this period was the organization of the Board of Trustees for the preservation of beautiful and historic places in Massachusetts. If Mr. Eliot did not originate this idea, he was, at least, the most active promoter of the scheme which is bearing good fruit not only in Massachusetts, but has been adopted in other states, and promises to save from desecration and defacement many spots in different parts of the country which deserve protection for their beauty or patriotic association. Out of this idea grew the plan to save the natural charms of certain well-known places about Boston and unite them into a consistent system of public recreation-grounds, and Mr. Eliot took the lead in organizing the Metropolitan Park Board, of which he was made the landscape-architect. These magnificent pleasure-grounds and parkways, comprising thousands of acres of wooded hills and meadow-land, river stretches and sea views, were largely selected by him, and as they will be developed according to the plans he has outlined, they will make a monument on which an older artist might be content to rest his fame. Four years ago he became a member of the firm where he had received his training, and in a great variety of work he has proved himself one of the most accomplished of designers. He had an intense appreciation of nature, but he always kept up his student habits, examining the outdoor world critically, and reasoning upon what he saw to establish principles which could be applied in practice. He realized the relative importance of natural landscape and of architectural work; he planned with a broad spirit so that he could adapt his rules to buildings and gardens without any danger of over-elaboration on the one side or an affectation of naturalness on the other. He liked system, symmetry and dignity where artificial construction was needed, but no one appreciated better than he what was picturesque in nature, or had a greater reverence for her broad scenic aspects. Mr. Eliot was not only a man of creative faculty, he was, as the readers of this journal know, able to give reasons for the faith that was in him. He had the ability to make a consistent and logical statement of his views and to express them clearly; but, beyond this, he had the gift of expression in a singularly effective style, so that some of his reports are as useful as his designs. The Metropolitan Park Report of 1893, and others which have followed, together with his writings for the press, embody such an amount of sound doctrine, effectively stated, that one regrets that he has not left more of this kind of work behind him. In short, he was well equipped in every direction, and it is no exaggeration to say that his untimely death is an almost irreparable loss to rural art in America, a loss that will be felt more keenly since it follows so closely after that of Calvert Vaux, Henry Sargent Codman and Philip Codman.

Mr. Eliot was a man of the most delicate and refined nature. He was reserved as scholars are, but his elevation of mind and dignity of character were apparent to all, and he had a gentleness of manner and thorough consideration for the feelings of others which won the affectionate regard of all who were familiarly associated with him.

## Early Flowers.

A CORRESPONDENT who writes some pleasant words about the frequent advice given in GARDEN AND FOREST to use more shrubs and herbaceous plants which bloom very early in the spring, remarks that while it is delightful to sit in an easy-chair before a grate-fire and read about gardening of this sort, it has many drawbacks in actual practice. There are sturdy little flowers that will brave the frosts of early March in this climate, but human beings are not quite as hardy as Snowdrops, and it is often impossible to enjoy these where they grow without the danger of contracting influenza or rheumatism. In the slow progress of an English spring, March does not differ materially from May, and the garden is not an utterly inhospitable and unwholesome place in February. But the historic blizzard that we all remember swept down upon us in March, and this is the season when the mud in country roads is hub-deep, while the ground freezes every night and thaws every day, with snow-squalls imminent any afternoon, and with rarely more than a few hours together, now and then, which have in them any warmth or genial promise. In the face of such discomforts it requires some heroic determination to tramp over spongy turf in overshoes to hunt up a flower, here and there, from little plants that have been naturalized in the grass or in a wood border. No doubt, there is some force in this view of the case, and elderly persons of rheumatic diathesis and persons of any age with a tendency to lung trouble would preferably be in Florida or southern California in the very earliest days of our so-called spring. Again, there are many persons who live in cities during the winter, and it may be advisable not to spend much thought on the decoration of home grounds at a season when none of the family can enjoy them, but to reserve all serious effort to brighten up the garden until a few weeks later. But frost and wind have few terrors for the enthusiast who wishes to test varieties of Reticulate Irises or certain new Scillas, *Chionodoxas* and others of the very earliest flowers; and even those who are not enthusiasts, and only care for a few specimens of the species and varieties which will make the most attractive show, are

sure to find a certain distinct pleasure in the cultivation of these very early flowers which the later ones never afford. The very hardships which these daring plants endure arouse our sympathy, their fragile appearance increases our regard for them, and, besides the welcome they receive as the forerunners of the abundant beauty which is to come as the season advances, they have a certain grace and refinement of form and a delicacy and a purity of color that the bigger and more showy developments of summer cannot surpass.

We must repeat, therefore, that, in spite of the many discomforts of the season, every one who lives in the country and has any garden whatever should arrange to make as much as possible of the early flowers, if not the very earliest, and have a spring garden. Many shrubs give a considerable floral display in early April, and these would make an appropriate border for such a garden, and many trees like *Prunus Davidiana*, our Swamp Maples, and a little later on the Redwood would show well in the background. *Corylopsis pauciflora*, with its pale yellow flowers, a relative of our Witch Hazel, is among the earliest shrubs to bloom, and *C. spicata*, which is hardy as far north as Philadelphia, has more showy flowers, with a distinct and pleasing fragrance. The early Jessamine has long arching branches covered with bright yellow flowers, and this, too, is hardy at Philadelphia. The Cornelian Cherry is a neglected shrub which flowers very early, and it is an interesting shrub all the year through, especially in the later season when its abundant cherry-like fruit is well colored. A little later *Fothergilla Gardeni*, a native of our southern Alleghanies, begins to show tufts of long white stamens at the extremities of its branches before the leaves appear. The Japanese *Andromeda*, with its panicles of elegant white flowers, and our still more beautiful *Andromeda floribunda*, both evergreen shrubs, are sufficiently beautiful for any situation. Neither the Yellow-root, *Zanthorhiza*, or Leatherwood has very conspicuous flowers, but they bloom early and would be useful in such a collection, and so would our native Currant, *Ribes aureum*, as well as *R. alpinum* and *R. saxatile*, all of which have handsome and fragrant flowers. For rock-work there is the lovely *Trailing Arbutus* and the sturdy little Heath, *Erica carnea*, and other shrubs might be named, like *Daphne Mezereum* and the bush Honeysuckles, *Lonicera fragrantissima* and *L. Standishii*, the Forsythias and our native Spice-bush, but these will suffice to brighten the shrub border until *Spiraea Thunbergii* and the great mass of spring-flowering shrubs begin to bloom.

A few of the hardy, herbaceous plants which were brightening Mrs. Dandridge's garden a fortnight ago are named in another column. Mr. Gerard has been telling us for weeks that there are many Irises of singular beauty and effectiveness, not to speak of the hundreds of varieties of bulbous plants which can be counted on for a display at this season. Many of these flowers are the perfection of delicacy in form and color, and they seem all the more satisfying because there are no other flowers to distract our attention or to compete with them for notice and admiration. A little garden of these early flowers in some sheltered spot never fails to please, and when no separate place is provided for them, and they are tucked away here and there at the base of a rock or along a wildwood path, they give us the added pleasure of a surprise as we come upon them unexpectedly. We have so often named the species most suitable for this climate that readers are referred to the indices of former volumes of this journal. *Bulbophyllums*, Grape Hyacinths, Spring Snowflakes and *Fritillarias*; *Anemones*, Violets, *Trilliums*, Bellworts, *Globe Flowers*, *Adonis*, *Corydalis*, *Cowslips*, *Primroses*, *Ranunculus*, *Epimediums*, *Eranthis*, Iceland Poppies—these are the names, in addition to those mentioned elsewhere in this number, which will first occur to one who thinks of a Spring Garden, and most of them are found in many varieties. But what the novice needs most is to make a beginning, and the time will soon come when his anxiety will

not be that he cannot find plants enough for his early garden, but that he has no room for even a small portion of those which he thinks he cannot get along without.

It is a misfortune that the effort to induce the authorities of California to recede the Yosemite Valley to the United States has failed. A bill drawn for that purpose was approved by the proper committee of the California Legislature, but was lost when it came before the House. Perhaps some of the criticisms upon the management of this wonderful valley have been too severe, but its sublimity as a whole, with the delicacy and beauty of its details, belongs of right to the people of the Union, and they do well to be critical when men without taste or training assume to improve such scenery. It is plain that the authorities of California have never realized the fact that the poetic charm of this place has an untold value and that there should be a complete and consistent policy of administration devised by artists in landscape design—that is, by men who not only “have good taste,” as the saying is, but who have studied problems of this kind, who comprehend what are the essential features which it is necessary to preserve, and who know how to treat the controlling elements of the scenery. It is no wonder that the people of the country read with horror that undisciplined men were turned loose at times with axes to clear away the underbrush and chop down trees, or that portions of the land had been leased out to hay contractors and hedged off by barbed wire fences. As we have said before, this scenery, unique for its combination of grandeur and beauty, belongs to the people, and it ought to be controlled by the Government, which represents all the people. There has been a special reason for this since the United States has established a forest reservation sweeping all about the valley and leaving this state property completely isolated. There is still more reason now since the establishment of so many more reservations by President Cleveland, for the increased importance of the reservations will necessitate the establishment of some fixed policy and will hasten the enactment of some sort of law for the government of these great tracts. This is understood as well in California as anywhere else, and many citizens of that state are strongly in favor of the proposed recession. Let us hope that when the measure once more comes before the legislature of that state the restoration of the land to its proper ownership will be accomplished.

#### The Garden in Relation to the House.

AT the meeting of the Royal Institute of British Architects, held on Monday, February 15th, 1897, Mr. H. E. Milner, the well-known English landscape-gardener, and Honorary Associate of the Institute, read a paper on “The Garden in Relation to the House.” As this is a subject which is now interesting both architects and landscape-gardeners in this country as well as in England, an abstract of the paper may not be unwelcome.

Mr. Milner said that he did not propose to set forth a history of gardening in England, but to state his own opinion as to the treatment to be adopted in laying out private grounds, particularly in regard to their more immediate relation to the house, and to indicate generally a practical application of the theories advanced. The utilitarian and necessarily small and formal garden enclosure of the middle ages was spoken of, and its gradual enlargement, until a high state of development was reached under Elizabeth, when the architect who designed the house, laid out the garden as well, with its fore-court and broad terrace, and its straight walks all harmonizing with the building. Yet the garden was still enclosed and little thought given to the treatment of the country outside, beyond the planting of avenues. In the end of the seventeenth century design began to deteriorate, and the ideal sought for was intricacy of parts, repetition and vagaries. Soon came a reaction, and toward the end of the last cen-

tury fashion ruled the destruction of most of the old formal gardens, to be replaced by a no less artificial imitation of nature. The designers, at this time, were not content with amalgamating whatever was good of the old work, with a natural treatment of the outlying ground, or of giving greater breadth to the existing formal work, but swept all this away and replaced it by meaningless walks; by clumps of trees and shrubs dotted irregularly on the lawn and park; by a boundary of planting; by imitation of bits of natural scenery or the introduction of artificial ruins and such like objects, with the desire of making a picturesque landscape.

Mr. Milner then spoke of the happy mean where the art of both schools should go hand in hand, the architect designing the stone or brick walls, steps and terraces, the landscape gardener taking charge of all the arrangements of verdure, and composing the wider picture. The author then pointed out the danger that the liberal art of true formal gardening might degenerate into a mechanical one in which problems are all treated after a certain set rule. Upon this point he said:

It must be borne in mind that places differ much in climate, in soil, in the requirements of the owner, in the amount to be expended, and in the possibility of an extension beyond their immediate precincts. It would, therefore, seem futile to lay down any hard and fast rules for design, for that which would be suitable for a plain would be inapplicable to a hillside; that which would be fitting to a peaty hollow would be wrong on a chalky slope; that which would satisfy the poor man would hardly be deemed sufficient indication of the wealth of a proud possessor; that which would inclose an oasis from the surroundings of factories, might shut off the lovely view of hill, dale and water, and imprison the dweller within a wall—possibly charming in itself, but tiring by restraining the eye from wandering to the unseen and glorious beyond.

In dealing with the details of the site, the approach, the terrace, the garden formation and planting, Mr. Milner spoke of the most advantageous aspect for a house in different parts of England, and his recommendation of a hillside rather than a hilltop for the location of a house is one which we would do well to take to heart:

The approach to a house should always appear to be direct, and any deviation from such directness should not only arise from, but should also be made to arise from, some decided obstacle. By direct is not meant straight. A straight approach requires careful treatment. It is artificial in character; it can appropriately be used when an imposing or somewhat pretentious building is at the end of it, or when the distance is short and when the country is flat. In sloping ground it should, if possible, be made against the slope of a hill. The gradient should be even and flat, or very slightly and continuously curved, otherwise it will appear not straight. If the ground is very undulating, a straight road is out of character with its surroundings. It may be worth mentioning that in laid-out grounds of Tudor times, even where an avenue has been planted, the drive has followed a curved line to the fore-court of the house. A curved line of road is generally to be preferred, for it is more easy of construction, more varied views can be obtained, its gradient can be varied, following within limitations the natural undulation of the ground, and the side slopes can be more easily and freely dealt with than the sides of a straight drive. At the entrance from the public road, and also where the road reaches the house, the route should be nearly level and the line straight. It should rise toward the house when approaching it directly, and it should be level at crossings or junctions. It should not run parallel with the public road with the mere purpose of lengthening the course, or seeming to prolong it, though, when the house is at a much higher level and the object is apparent, this resource must be sometimes adopted.

Having touched upon the engineering of road gradients and construction, Mr. Milner spoke as follows of the lodge and entrance gates and terraces:

These belong to the drive and should be parallel with it and at right angles to it, as distinguished from the highway. The face-line of the lodge should be at least ten feet from the edge of the drive, and its windows should be able to command the entrance and a certain length of drive. On entering by the drive it is advisable to create a good impression, and therefore the difference between the dusty highway and the shaded, well-trimmed drive within the gates should be distinctly

marked. Planting may be introduced on either side of the entrance, but once well inside, a view should be given of the outlying grounds, or stretch of park, or distant wood. A curved drive should not be planted continuously, but broad masses of planting may be introduced, at first to shut off the highway, at turns in the drive, and on the top or slopes of knolls round which the drive may wind.

The treatment of the terrace depends very much on the architectural character of the building. By "terrace" I mean not only the narrow strip of level ground placed parallel with the house, or the more stately portion—often with architectural adornments—that is laid out along the face of the structure, but the whole of the ground that forms the base or setting of the building. A great divergence between the work of English and foreign landscape-gardeners is to be seen in their several methods of dealing with the ground immediately surrounding the house. In England we insist that the treatment of the ground next it shall be artistically formal, with regular lines of turf, wall, slope, walk or bed, all displaying harmony, as far as may be, with its architectural character. On the Continent, with some important and notable exceptions, they surround the house with broad, irregularly curved spaces or walks that have nothing in common with the design of the structure. By one practice the endeavor is to give a base to the building and to create on the contiguous ground an expression of kindred artistic spirit; by the other, the ground is treated as something apart, and a feeling of unrest is created.

Various forms of terrace were then discussed, and Mr. Milner passed on to the treatment of the garden proper, quoting in part from a book of his own, published about seven years ago:\*

So many considerations press in to vary general design in the general plan of a garden that arbitrary dealing by imposition of what may be termed paper designs, however ingenious, is ill-advised. The detailed plan should spring from the site as an adaptation of its natural or created features, and should not be, as it were, forced upon the position, crushing it to an artificial scheme. To copy simply the design of another place is inadmissible. Considerations that rule in this connection are almost infinite—extent, geological formation, soil, existing natural formation or features, climate and aspect, the display of distant beauty, conformity to outside influences, particularly to the requirements of the possessor and the expenditure of money that may be made. It is this important variety of modifying influences, and how they are dealt with, that gives charm to each new work of landscape-gardening and to the development it presents; just as we contemplate a fresh work of the kind in pictorial art, and note how the artist has treated the natural features, the colors and tints and their modifying juxtaposition on the canvas. The painter may, indeed, have his rules as to composition, for the use of his colors and the production of his distances. His picture is not a servile copy of nature in its exact details, but an artistic rendering of the effect of nature, as seen by his educated eye and recorded by his skillful hand. His picture, however, is viewed from the same point; but in the natural pictures created by the landscape-gardener the point of view is on every side; there is no back to his canvas. In each position the object should be one of beauty, of interest and of delight, and its relation to other features and to the whole field of the spectator's vision be closely and truly considered. The landscape-gardener must consider that his colors change and grow; he must realize as he creates his picture that in a few years what now seems like a light green stroke of pigment to the painter may have become a tall tree, beautiful in itself, but of altered beauty, either helping or marring the landscape. He follows nature by adapting or garnering her beauties, and tutoring her, so to speak, to a display of them. But by following nature is not meant a slavish imitation or reproduction of any of her particular scenes. Some are unattractive, some very inappropriate; all are subject to dissimilar conditions, and imitation in nature as well as in art produces pettiness. But the spirit of the beauty of nature, embodied as it were in those of her works or features that express her majesty, simplicity, peacefulness, sweetness, repose, refinement, strength, and variety in form, color, abundance, or any of her modifications as parts of loveliness, should be included and brought into juxtaposition in an ideal scene so far as we are able to promote its natural development.

On the grouping of trees for effect, Mr. Milner says:

When the ground is broken or undulating (either natural or created), advantage should be seized of marking the eminences

by planting. Rising ground may be in appearance raised still higher if we cover it with wood. Trees standing singly emphasize falling ground. The brow of an eminence should not be seen above trees. If the brow forms a tedious line, it should be broken by clumps or large masses along its range, and by dividing the line into very unequal parts.

In conclusion, I maintain that we should carry out in the parts surrounding the house the architectural feeling of the design in terraces, walls, steps, basins, beds, and so form a base; that we can still have the dignified and quiet delight of formal work—not a narrow curtailment of the whole design. But I insist that there is in addition a broader treatment beyond—a work difficult to proportion in relation to foreground, to broad lawns, spaces, to grouping and choosing trees and shrubs for effect in size and color, to directing the eye to desired points, to taking advantage of climate and character of the place either natural or acquired, to provision of light and shade in the undulation of the ground, and to a knowledge of horticulture. This art-gardening is, I venture to assert, far beyond the limitations of formal work only, for it can apply the balance and proportion of the matter, and, in addition, present to us a noble conception of art-work, in its execution of outline, surface formation and grouping, and draw into the picture the greater, broader, varied landscape.

Mr. Milner's interesting paper recalls to us the present necessity for remembering that the arts of architecture and landscape-gardening are sisters, not antagonists, and that the work of the architect and landscape-gardener should be done together from the beginning, one supplementing the other, but not, as too often happens, one crowding the other out. The architect is apt to make light of the importance of the treatment of the ground after it passes his own immediate connection with it, and may consider that the landscape-gardener does small justice to the setting of his house. The result can only be satisfactory when the two artists work side by side and in sympathy from the outset, and neither attempting to go beyond his own legitimate limits. There is still too little of this collaboration, and too little sympathy between the professions, each now fearing the interference of the other. It will be a great step in the advancement of both arts when the architect and landscape-gardener shall, as a matter of course, decide on the site of the house together, helping each other to arrange a base for the building; and also when the beauty of broad landscape treatment shall be recognized, as well as its necessity for the completeness of an artistic whole.

New York,

Beatrix Jones.

## Foreign Correspondence.

### London Letter.

**CEPHALANDRA MACKENII.**—*Cephalandra* is allied to *Cucurbita* and includes about a dozen species, all African, one, *C. Indica*, known also as *Coccinea Indica*, extending to India and Malaya. They are Bryony-like climbers with perennial root-stocks, angular or lobed green leaves, dioecious, bell-shaped yellow or white flowers an inch across and smooth fleshy drupe-like fruits from one to three inches long, usually of a brilliant scarlet color; they contain a large number of ovoid compressed seeds a quarter of an inch long, broad and flattened at one end. They are usually bitter like *Colocynthis*. *C. Mackenii* is wild in Caffraria, where it scrambles over trees and shrubs and bears large numbers of bright scarlet sausage-shaped fruits three inches long; the leaves are palmately lobed and three inches across. In the garden of Mr. Hanbury, at Mentone, it is a valuable evergreen climber, flowering and fruiting most profusely. Planted against a south wall it covers a space twenty yards square in a few months. I have lately received a box of the fruits from that garden. *C. Indica* requires warm greenhouse treatment at Kew, and probably *C. Mackenii* will thrive with it. Cultivators must not overlook the fact that these plants, being dioecious, must be represented by individuals of both sexes.

**SICARA ODORIFERA.**—I have lately seen in American papers references to this Cucurbit under the name of "Casabanana," and it is recommended as an edible fruited gourd. It has

\* *The Art and Practice of Landscape-gardening*. By Henry Ernest Milner. Marshall Hamilton, Kent & Co., Ltd., London, 1890.

been grown in Europe since 1862, when it was introduced into France from Peru and cultivated with success by Monsieur Naudin, the author of the name. The fruit is cylindrical, four inches long by nearly two inches in diameter, of a rich orange-red color when ripe. It exhales a powerful apple-like perfume, and, according to Sir Joseph Hooker, it is used in America as a preservative against the attacks of noxious insects, both from the person and from garments, etc. But I have never heard of its being eaten. A second species, *S. atropurpurea*, was described and figured in the *Revue Horticole* in 1894 by Monsieur Ed. André, who introduced it from Uruguay. It has fruits five inches long, pale claret-colored when ripe, and apple-scented. Monsieur André recommended it as an elegant green-leaved climber and for cultivation on trellises in southern Europe. The plant grown in the United States as *S. odorifera* is said to have fruits a foot long. Can any one send seeds to Kew of this American plant, the "Casabanana"?

**HODGSONIA HETEROCLITA.**—This magnificent perennial Cucurbit has been in cultivation at Kew for at least twenty years, and although it grows with a vigor equal to that of wild plants, it has never yet flowered. It is a native of low elevations in eastern Bengal. Sir Joseph Hooker named, figured and described it in his *Illustrations of Himalayan Plants*, tabs. 1-3, where we are informed that its stems grow to a length of a hundred feet or more, climbing the forest trees from which it sometimes hangs and forms a dense screen of dark green plane-like foliage. The flowers are large, red, brown and yellow outside, white inside, about four inches across and surrounded by a hanging fringe of tendril-like filaments four inches long. They are produced abundantly by wild plants and often may be seen strewing the ground in the forests, although the stems are lost in the vegetation above. It is, perhaps, the most striking in flower of all the Cucurbitaceæ, and I call attention to it here as the conditions in the southern states, say California for instance, are likely to suit it better than those of this country.

**SNAKE GOURDS.**—Several species of *Trichosanthes* are worth including among ornamental climbers for the stove. They grow quickly, seeds sown in March producing plants which will be fruitful in July if grown in a moist sunny stove where their stems can be trained along rafters so that the fruits can hang well in view. It is necessary to see that the female flowers are fertilized artificially, as the plants are usually dioecious. At Kew these and similar tropical Cucurbitaceæ are grown in the same house as the Water-lilies, where they are planted in a narrow border and the stems trained to wires over the tank, where, when the fruits are ripe, they make a striking and novel show, hanging like brilliant-colored snakes from the roof. The best are *T. anguina*, with fruits a foot long; *T. colubrina*, with fruits two feet long; *T. cucumerina*, with fruits like small cucumbers; *T. palmata*, with globose fruits the size of small oranges. They are all scarlet, with streaks of yellow, white and green. The flowers are large, white, with the corolla lobes divided into hair-like filaments.

**CRASSULA ALOIDES.**—This very interesting new species of *Crassula* has been introduced to Kew from the Transvaal, where it was discovered on hillsides in damp places near Barberton at an elevation of from 2,000 to 4,000 feet. According to Mr. E. Galpin, who sent seeds of it to Kew in 1891, it grows to a gigantic size, with a thick, unbranched, Aloe-like stem bearing a rosette of fleshy, lanceolate, bright green, flaccid leaves a foot or more long, nearly three inches broad at the base, and tapering gradually to a long recurved point; they are much like the leaves of an Aloe, and not at all like any *Crassula* known to me. The flowers are equally remarkable, being borne in a dense corymbose head eighteen inches in diameter on a peduncle three to four feet high, and they are colored cream-yellow. At Kew this plant thrives only when kept in a moist stove and shaded from bright sunshine. No one unacquainted with it would hesitate to call it an Aloe, or some closely allied plant. It excites as much interest at Kew as

*Richea pandanifolia*, an *Epacris* with the appearance of a *Pandanus*.

**PODOPHYLLUM PLEIANTHUM.**—This remarkable plant was discovered in the island of Formosa in 1881, and four years later it was introduced to Kew, where it flowered, and was figured in *The Botanical Magazine*, t. 7098. It is a near ally of the North American Mandrake, May-apple or Duck's-foot, *Podophyllum peltatum*, but differs markedly in having a cluster of about a dozen large drooping flowers springing from the axil of the pair of large peltate, lobed, glossy green leaves, and in their deep purple color. Last year some plants of it were placed in a sheltered border outside against a greenhouse, and they have survived the past winter without protection. It is also grown in a cold greenhouse, where it produces leaves a foot in diameter and its odoriferous flowers in August. *P. peltatum* and the Nepalese *P. Emodi*, a pink-flowered species, are grown successfully in the open air at Kew, where they ripen their large bright red fruits in autumn. *P. pleianthum* is a handsome as well as interesting addition to herbaceous plants suitable for cultivation in borders.

**YELLOW RICHARDIAS.**—Some cultivators in this country have failed with the two yellow-spathed *Richardias*, *Elliottiana* and *Pentlandii*, though treating them as cool greenhouse plants, and others through keeping the tubers quite dry during winter. My experience is that they must have warm greenhouse, even stove treatment, while growing, and when at rest they should be kept in moist soil, as we keep *Caladiums*. All tuberous-rooted Aroids, without exception, are better rested moist than dry; indeed, this treatment is in accordance with the conditions under which they grow naturally. Last year I planted six small tubers of *R. Pentlandii* in a border in a moist stove where tropical Water-lilies are grown, and they grew with exceptional vigor, the tubers being as large as a child's fist when lifted at the end of the season. Our plants were started a month ago in a stove, and they are now growing strongly. With these two exceptions, all the *Richardias* may be grown in an ordinary greenhouse or frame along with such plants as *Pelargoniums*.

London,

W. Watson.

## New or Little-known Plants.

### *Sambucus melanocarpa*.

THIS shrub (see illustration on page 135 of this issue), which was long confounded with the red-fruited *Sambucus racemosa* of high northern latitudes in both the New and Old Worlds, was first distinguished by Gray in the *Synoptical Flora of North America*\* by its black fruits, more convex clusters of whiter flowers and less pubescent foliage. In habit and in the shape of the leaves the two plants are very similar, and it is practically impossible to distinguish them, except when the fruit is ripe.

*Sambucus melanocarpa*, which attains a height of five or six feet, is common in the northern Rocky Mountains, where it grows near banks of streams and on the sides of moist cañons usually at elevations of from three thousand to eight thousand feet above the sea-level, and flowers from May until July. It is common, according to Macoun,† from the valley of the Columbia, near Donald, in British Columbia, through the Selkirk Mountain region, growing on the beds of snow-slides and in damp thickets. It is abundant in northern Montana and Idaho,‡ and in the Yellowstone National Park in the neighborhood of the Mammoth Hot Springs; and it was reported by Gray as growing on the mountains of eastern Oregon, southward to the Wasatch Range in Utah, in New Mexico, and on the Sierra Nevada of California.

*Sambucus melanocarpa* has not yet been tried in our gardens, where, no doubt, it will prove hardy.

Mr. J. B. Leiberger has recently separated from *Sambucus*

\* i. pt. ii., 8 (1884).

## Cultural Department.

### Chrysanthemums.

OUR Chrysanthemums intended for specimen plants are now in four-inch pots. We are later than usual this season, as we intend to finish our plants in ten-inch pots. With lessened pot-room the growing season is shortened. When we have used twelve-inch pots we have made the final shift

during May, but this would be too long a season when smaller pots are used to finish them in. By easy stages we shall transfer our plants into the flowering pots by the middle of June. In the mean time the plants will need careful stopping to insure sturdy growth. To get low, well-balanced growth we must begin now to make a foundation. It is not a work which can be arranged by the week or month, but must be attended to daily. There will always be an abundance of leading shoots, and if these are allowed to get away it will be at the expense of the side shoots. A lateral growth is desired at all times, for it is far easier to train the shoots upward than outward.

We pot firmly, but do not pack the soil. Our experience has shown that the roots of large, healthy plants when confined, as they are in pots, increase the bulk so much that but little room is left for water, especially toward the end of the season. Sometimes the roots choke up the drainage, and last season we had to drill holes in the sides of several pots which had become waterlogged. We advise that three holes be made in pots intended for specimen Chrysanthemums; this can be made with a sharp-pointed chisel. In potting it is well to allow at least two inches for water. This makes it convenient to give a top-dressing to some of the less thrifty plants late in the season.

Our stock plants for specimen blooms are still in cold frames. They will soon furnish an abundance of cuttings. All early varieties, such as Madame Bergmann, Marion Henderson and Glory of the Pacific, may be taken during April. May will be early enough for midseason varieties, and June for close planting, where medium-sized blooms only are wanted.

For propagating we use a frame which can be kept closed during bright days, and well shaded. We air thoroughly during the night. Plenty of water is required for the first week or ten days, and the cuttings should not be allowed to wilt.

Wellesley, Mass.

T. D. Hatfield.

### Carnation, Chabaud.

**SUMMER-FLOWERING** annual Carnations are of quite recent origin, and it is only about five years since the Marguerite strains were introduced and accepted with much caution by cultivators, for it did not seem possible that they could be brought into flower from seed in so short a time. There has not been any apparent improvement on the Marguerite strain since its introduction; on the contrary, there seems an even greater tendency to the production of single flowers than when first sent out. I have noticed that a large proportion fail to flower the first season, and it is evident that the strain has not been perpetuated with as much care as it deserves.

The Chabaud strain of annual-flowering Carnations was therefore a valuable addition. These seem to combine all the good features of the older Carnations, such as free flowering, diversity of color, fragrance equal to the indoor varieties, and good yellow varieties occur quite frequently. This is one of the few sterling novelties that cultivators are always seeking, but do not succeed in finding with all their purchases.

Annual-flowering Carnations should be sown early in the year if they can be sown under glass. Treated in this way the flowers will be most satisfactory, but it is by no means too late to sow now, as there will be rapid growth during the brighter and longer days. We made a sowing last December to see how large it was possible to have them and how early in the summer, but another sowing made now will lengthen the flowering period considerably in the late summer months, when flowers are scarce.

South Lancaster, Mass.

E. O. Orpet.

### California Garden Notes.

**Antholyza Æthiopica.**—This is a showy bulbous plant common in gardens of southern California, and it blooms freely during the winter months. It belongs to the Iris family and produces a spike of flowers with foliage like that of *Gladolus*. It is a native of south Africa, and is commonly known in gardens, I am told, by the name *Watsonia*, a nearly related genus. The spike of flowers is generally over four feet tall, with as many as thirty flowers on one of its two branches, the flowers of a dull brick color or Chinese red, the prominent anthers and markings in the divisions of the corolla of a deep maroon. The flower is more than two inches long and nearly an inch across.

**Scilla hyacinthoides.**—This *Scilla*, a native of southern Europe and Palestine, is rare in our gardens, but thrives well. Its spike of blue flowers is sent up to a height of about three

feet from a mass of luxuriant foliage, and bears from 100 to 150 or more light lavender-colored flowers, each nearly three-quarters of an inch across. The long spike of flowers opens in succession, and thus remains in bloom for a long period of time.

**Leptosyne maritima.**—This is one of the showiest of the flowers that bloom with us in March. The luxuriant mass of succulent foliage is surmounted by a wealth of its rich yellow flowers, which measure fully four inches across and possess a delicacy of texture rare in a composite. Its flowers should be popular for cutting, but it still seems not to have found a place in many American catalogues. Its tuberous roots may be easily handled, or it may readily be grown from seed.

**Freesia refracta alba.**—This *Freesia* has been a disappointment to some of its eastern friends who have tried to grow it from seed, expecting it to blossom the first season, as some catalogues have claimed it will do. In my own experience the character of the soil seems to make all the difference in the results obtained. In some of our mesa soils it makes a better bulb and produces finer flowers in one season from seed than it will in several seasons in our rich valley soils, and only experience can determine its needs in this respect.

C. R. Orcutt.

### American Shrubs for Ornamental Planting.

TWO weeks ago GARDEN AND FOREST published an article entitled "American Trees for Ornamental Planting," which was a summary of part of a lecture delivered by Mr. B. M. Watson, of the Bussey Institute, before the Lenox Horticultural Society. I now send a condensation of what Mr. Watson said of certain native shrubs, repeating what was stated in relation to the trees that this does not pretend to include all the American shrubs which are worth planting. Nor must it be inferred that imported shrubs should be excluded from American gardens, for many of them are very desirable. The aim was to call attention to several of our neglected shrubs, with a brief statement of some of their leading characteristics.

*Azalea* still remains the popular name for the deciduous section of the *Rhododendrons*. The hardy kinds most generally planted are known as the Ghent *Azaleas*, which are hybrids of our native *Rhododendron* (*Azalea*) *calendulaceum*, a plant of the southern Alleghanies, rather larger than its hybrids and quite as well growing for its brilliant flame-colored flowers. When propagated from seed its flowers show a variety of colors. It needs a rich soil and a deep one, with water in summer and some protection in winter until it is established, and then it is perfectly hardy. Our Pinxter-flower, *R. nudiflorum*, is rarely planted, but it is well worthy a place in the shrubbery, for its bright pink flowers, which also vary, widely among many seedlings, are most attractive in the early seasons. *R. arborescens*, also from the southern Alleghanies, has white fragrant flowers slightly tinged with rose, and brilliant scarlet stamens, which appear in early summer. *R. Vaseyi* is a comparatively new plant, but it is rapidly gaining favor, and it is probably the best of all our native *Azaleas* because it flowers so early and is less liable to be cut back in the winter. In growth it is regular and bears an abundance of beautiful pink flowers before the leaves expand. This ought to be a capital subject for the hybridizers. All these plants are now to be procured in abundance at reasonable prices since they can be collected easily in the Carolina mountains. *R. viscosum* flowers in July; that is later than the other species. It is our common Swamp *Azalea* with white flowers and exquisite fragrance. It naturally grows in wet land, but when lifted from the woods it succeeds admirably in the garden.

*Baccharis halimifolia* sometimes assumes the form of a small tree, and it is one of the few shrubby plants which belong to the great composite family. It is naturally a beach plant, but it grows well anywhere, and is most interesting on account of its good foliage and its numerous cottony fruits in late autumn. Mr. Olmsted has used it largely in planting the Back Bay fens in Boston, where it is sometimes badly cut back in winter, but the annual growth is rapid and sufficient; indeed, close pruning seems to give the best development of its foliage and fruit. *Cephalanthus occidentalis*, the Button-bush, is especially desirable because it blooms late in the summer. Usually found in moist places, it is always thrifty in or near the water, but it grows also in well-drained soils. *Clethra alnifolia*, the Sweet Pepper-bush, is another late-flowering shrub and a charming one, bearing an abundance of snow-white flowers in spikes. It will grow anywhere, even in shade or in poor soil, and is an excellent undershrub. The southern species, *C. acuminata*, makes a pleasing variety.

Besides the well-known Flowering Dogwood, *Cornus florida*, which is a small tree, there are many others of our native *Cornels* which deserve a place in parks and gardens. *C. alternifolia* is a tall shrub or small tree with a singular and beautiful arrangement of branches. *Cornus circinata* has large, rich foliage; *C. sericea* has dark red twigs in winter and is a delightful addition to the Red Osiers, and all the species have abundant flowers, fair fruit, are easily handled and do well in almost any situation. *Dirca palustris*, the Leatherwood, is a compact shrub of medium height, with small yellow flowers in very early spring, and the peculiarity of its long tough twigs is curious and interesting. *Evonymus atropurpureus*, as well as *E. americanus* and its variety *obovatus*, are not often planted, and yet they are quite equal to the European Burning Bush, which is an old favorite in gardens. *E. atropurpureus* is probably the very best of the genus. *Hammamelis Virginica*, the Witch Hazel, is one of the very best of shrubs for its symmetrical growth and good foliage, while in late autumn, even after frost, its yellow flowers on the leafless branches give it unique value. It is hardly ever planted, and yet where a large and easily grown shrub is required, either for a single specimen or in a mass, the Witch Hazel ought to receive consideration. *Ilex verticillata*, the Black Alder, is among the very best of our plants for bright berries, which remain in good condition from the time the leaves fall until midwinter. Its foliage and habit of growth are both good, and although naturally growing in wet soil it succeeds quite as well in dry. It is easily handled, too. Wild specimens which show abundant berries can be selected, divided and transplanted, or they can be propagated by seeds. The fruiting capacity is improved by cultivation. A yellow-fruited form is now established well in the Arboretum.

*Leucothoe racemosa* is a shrub of medium size with white flowers in racemes, which are much better on cultivated plants than on wild ones. The chief beauty, however, of this shrub is its dark green leaves in summer, which turn to fine reds and purples in the fall. Associated with *Vacciniums* and *Zanthorhiza* delightful effects in autumn coloring can be produced. *Lindera benzoin*, the Spice-wood or Fever-bush, shows its yellow flowers before the leaves appear, and is interesting for its early bloom. It is a tall, well-shaped shrub with fine dark green foliage and bright red fruit. *Myrica asplenifolia*, the Sweet Fern, and *M. cerifera*, the Bayberry, are both good plants for many situations, and especially useful to cover and hold the soil of slopes on cuttings and embankments, for they will thrive in the poorest soil and under generally unfavorable conditions. The foliage of the Sweet Fern is very distinct, and that of the Bayberry glossy and beautiful, while its fruit is interesting. The Sweet Gale (*M. Gale*) is adapted to the borders of ponds and brooksides, and the color of its twigs is effective in winter. *Nemopanthes fascicularis*, the Mountain Holly, is not at all evergreen as its common name might imply. It is a handsome, much-branched shrub, however, with good foliage and fruit. *Potentilla fruticosa* is a low shrub, bearing loose clusters of showy yellow flowers in summer, and its glaucous green foliage makes a pleasing contrast with other plants in the shrubbery. *Prunus maritima*, the Beach Plum, is another plant which grows well in sterile soils and exposed conditions, especially on the seacoast, since it is sturdy enough to endure the strong winds that blow over large bodies of water. Under more favorable conditions and when well grown it makes a symmetrical shrub of medium size and sometimes a small tree. It is covered with beautiful white flowers just before the leaves open, and the attractive fruit, ranging in color from amber to bright red, is good enough in many individual trees to eat from the hand, and it is also good enough for preserving. *Pyrus arbutifolia* and *P. nigra* are two species of Choke-berries, interesting shrubs of the Rose family, from two to six feet high, which are most effective in masses. The fruit and foliage of the red-fruited form make a happy combination of color in October. The dark-fruited species is a plant somewhat smaller, with fine, glossy deep green leaves, abundant fruit, and is easily grown in sterile soil and in exposed places.

The Sumachs are most desirable for the effect of their foliage in summer and autumn, while the warm color of the fruit and twigs of some of the species gives additional interest to them in the winter. *Rhus Canadensis* (*aromatica*) is a low bush which almost creeps over the surface of the ground and is well adapted for use on the edge of shrubberies, and is useful in covering exposed banks. Its numerous small yellow flowers appear in early spring, and its foliage, which is always good, is particularly fine in autumn colors. The so-called Dwarf Sumach, *R. copallina*, really becomes in rich soil a large-sized, symmetrical shrub with the brightest of glossy green foliage which turns to brilliant colors in autumn, especially if

it grows in poor soil. *Rhus glabra* makes a little larger shrub than *R. copallina*, and in some ways it is the best of the group, its very long compound leaves making it especially valuable for masses. The Staghorn Sumach, *R. typhina*, is the largest of the genus, making sometimes a tree thirty feet high. It endures pruning well and can be thus kept at any desired height. It is conspicuous, like the others of the genus, for its bold leaves and brilliant autumn colors. All these plants are strong growers and are at their best when massed together and kept by themselves. They make fine backgrounds for other shrubs or herbaceous plants and they succeed anywhere.

Single Roses are now much sought by planters since the introduction of the Asiatic *Rosa rugosa*, *R. multiflora* and *R. Wichuraiana* has called attention to the beauty of our own wild Roses, which had been overlooked. *R. Carolina*, *R. lucida*, *R. nitida* have been extensively planted in the Arboretum, and they are not only interesting for their flowers in summer, but for their bright red twigs and fruits in winter. They, too, ought to be planted in masses, and occasional severe prunings will be beneficial to the stronger-growing sorts and will keep them in good condition. *R. setigera*, the Prairie Rose, is a noteworthy addition to the above group, since it does not come into bloom until July. It is a large plant, and can be grown either as a shrub or a climber. *Rubus odorata*, the Wild Raspberry, is one of our commonest native plants, and is a useful one to grow in shady places. The foliage is not good, but it succeeds where few other plants can grow. *Sambucus Canadensis*, the common Elder, is a striking shrub of medium size and will grow anywhere, and its bold foliage and abundant flowers after the most of our shrubs have passed their bloom make a striking display. Its fruit is showy, too, and has some culinary value. The Red-berried Elder, *S. racemosa*, is also a delightful shrub, with flowers in early spring and bright-colored fruit in summer. These are symmetrical plants when well grown, and are suitable for planting in masses in parks or elsewhere. *Symphoricarpos vulgaris*, the Indian Currant, is one of the very best of shrubs where a low, thick mass of foliage is required. The running stems will quickly produce a verdant covering for sterile soil. The foliage is of the very best, and the slightly drooping habit of the branches makes this plant graceful in the extreme. The fruit is also noteworthy, but not so conspicuous as the white fruit of *S. racemosa*. *Vaccinium corymbosum*, the Swamp Huckleberry, or High Blueberry, one of our most ornamental shrubs, is of sturdy growth and excellent habit. The foliage is good all the summer, and in autumn its color is particularly brilliant, not excelled, indeed, by that of any other plant. The fruit is valuable, though it varies greatly in size and quality, and it seems to be the best of the species for experiments with a view to improving its edible qualities. *V. vacillans* and some of the other *Vacciniums* are also worth planting. *Zanthorhiza apiifolia*, the Yellow-root, is a dwarf-spreading shrub of compact regular growth, with compound leaves of good form and texture, which are particularly beautiful when they turn to purple and yellow in autumn. This shrub can be successfully grown in the shade, and it is a first-rate one to use on the border of a shrubbery to connect the grass with the taller specimens. GARDEN AND FOREST has so often described the American *Viburnums* and advocated their planting that I will not repeat what has been said about them. There are a dozen species, each one of which is effective at some season, and most of them at all seasons. They have good foliage, good flowers, good fruit and good habit. They can all be propagated from seed, although the germination does not take place usually until the second year, and they all improve under care and cultivation.

### Scillas and Chionodoxas.

AMONG the early flowers there are none more precious and desirable in the garden than the Scillas and their allies, the Chionodoxas. There is always a woodsy air about these flowers, and I believe they mostly grow in thin woods of deciduous trees. They vary considerably in form of flower and foliage, and though typically they are blue or blue-purple flowers, most, if not all the species, have white and red-purple forms. At this time, when the borders are quite bare of foliage, flowers whose colors harmonize agreeably with the soil are most effective. Yellow flowers are cheerful at any time, but like the white ones, require a certain amount of green foil to be altogether satisfactory. Spring-flowering bulbous plants have sparse foliage; those that have white and yellow colorings in the flowers are better grown either in grass or under some low-growing herbaceous plants. But the purple

flowers harmonize perfectly with the bare earth, and whether there is a lone plant or a coloring of hundreds in the border there is a natural, harmonious effect very satisfying to any one sensitive to the quieter influences of the garden. *Scilla bifolia* and *S. Sibirica* are the earliest to flower, and of these species the *Asia Minor* or *Taurian* forms are in advance. The form of *S. Sibirica*, known now as *multiflora*, is nearly over before the usual type begins to expand. A very pretty white form of *S. Sibirica* seems to be earlier than the type, as it is now in flower. This is a graceful habited flower, but not quite equal in purity of color to *S. bifolia alba*, whose star-like, upturned flowers suggest *Chionodoxas*. There is also sometimes in the garden a pleasing white *Scilla* with small hyacinth-like flowers, received as *S. amœna*. But these white forms are only oddities; the effective ones are the purple-flowering kinds. Those already mentioned, with *S. puschkinoides*, make a beautiful trio. As the season advances we have a succession of *Scillas*, such as *S. nutans*, *S. patula*, *S. campanulata*, etc.

The *Chionodoxas* have not yet a place in all gardens, though they are invaluable in early spring in bare borders, where they will thrive and maintain themselves under hard conditions. We have now, thanks mostly to Mr. Whittall, a rather wide variety of these flowers. The best blue of these are *C. Sardensis* and the same species with a dark eye. *C. Tmolusi* may be considered a dark-colored form of *C. Lucillæ*, which species, while the commonest, is one of the most effective, with large star-like flowers whose petals are more or less deeply tipped with blue in various shades. There are also daintily colored forms of these—very light blue, rosy and white—which are exquisite, not growing in large colonies at present. The large-flowering forms, *C. grandiflora* and *C. Alleni*, are much alike, scarcely to be maintained separately in the garden. They may be considered a distinct kind with large, but not as plentiful, flowers as other species. These flowers are a slaty light blue, and *C. Alleni* has traces of a lighter centre. Grown under glass this centre becomes so pronounced that the flowers resemble those of *C. Lucillæ*. *C. Cretica* is another species, but its small flowers are not pure in color, and it is scarcely worth growing. *Chionodoxas* and *Scillas* are so closely related that hybrids, even natural ones, are not uncommon.

## Correspondence.

### Notes from West Virginia.

To the Editor of GARDEN AND FOREST:

Sir,—One must live in the country all the year round to find how interesting a garden can be made in March with the earliest flowering shrubs and plants. Here at Rose Brake we have done much to make the grove and waste places of the grounds attractive by using our native wild flowers and naturalizing such foreign plants as take kindly to our conditions. Bloodroot, Twin Leaf (*Jeffersonia*), Dutchman's Breeches and many other easily transplanted wild things have a singular charm, and parts of our Oak grove are thickly carpeted with these plants and Violets. Here and there among the rocks the sweet-scented English Violets have formed colonies which are the first to bloom, followed by *Viola cucullata*, *V. pedata*, *V. blanda*, and here and there a clump of *V. sagittata*, so that we have Violets from the middle of March to the end of May. The Twin Leaf increases rapidly and its large white blossoms are associated with the still more purely white Bloodroot, which precedes it by a few days. It can be easily transplanted in early spring, and if carefully removed without disturbing the roots it will flower as abundantly in one place as another. This is true of the *Dicentras*, *D. cucularia*, *D. Canadensis* (Squirrel Corn), and many other common flowers which only require a mass of earth removed with the roots when the ground is softened by some spring rains. Crocuses by the hundred are naturalized in the grass on the lawn, and although they do not increase rapidly they certainly do not diminish; they are improved, however, by rich soil and cultivation, as seen by the superior size and beauty of the groups planted in garden beds. We have tried all the species and varieties, except the costly rarities, so that we have the early sorts in bloom here by February, while the later ones make a good show until the middle of April. Of course, there are colonies of Snowdrops, Snowflakes, *Chionodoxas*, *Scillas*, Daffodils and Irises naturalized here and there in secluded spots under trees and in rocky soil in the grove, garden and orchard, where they charm us by their unexpectedness as we chance to come upon them in full bloom bending before the rough breezes of March. The evergreen plants have a cheerful look in the rock-garden, and we now have a few flow-

ers from the Hepaticas, Hellebores, Rock Foils, Saponarias and Thymes, while here and there the Saxifragas, Spring Adonis and *Eranthis hyemalis* are flowering, and, of course, the hardy Candytufts and Creeping Phloxes are a mass of flowers and verdure. Our common wild *Saxifraga Virginica* is often found blooming early in the spring about moss-covered rocks among Ferns and Rue Anemones, but there is a great number of species and varieties to be had from European plantsmen. I now have a variety of *S. cordifolia* in bloom, which is labeled *Smithii*, with handsome foliage, dark green leaves, somewhat liable to decay under the winter protection of forest leaves, and clusters of bright pink flowers. Not to be despised is the common Periwinkle, *Vinca minor*, for the cheerful green of its new leaves and the bright blue of its flowers as they twinkle in the sun after a shower. The plant, however, is such an aggressive grower that it must be used with discrimination. It can be effectively employed on rough banks and in shady places where grass does not flourish, and here it will quickly kill out less sturdy plants and give a carpet of dark verdure all summer long when out of bloom.

Rose Brake, W. Va.

Danske Dandridge.

### Nursery Notes from Flatbush, Long Island.

To the Editor of GARDEN AND FOREST:

Sir,—The quaint old Dutch town of Flatbush, until last year a suburb, but now a part of the city of Brooklyn, contains more than thirty nurseries. Some of these are in groups, and thus conveniently accessible, but only a few can be visited in a day, since they are scattered over the township, which, even in the less remote parts, is but sparsely built up in detached dwellings, with stretches of newly plowed fields and here and there a low, old-time farm-house. At the beginning of Flatbush, near Prospect Park, is the establishment of Charles Zeller's Sons, containing five acres in trees, shrubs, glass houses, frames and beds. For ten years this firm has experimented with Pansies, and they have a choice strain of the very largest sizes and most beautiful colors. Nine frames, five by thirty-five feet, made a showy effect last week, and they sell 10,000 of these plants during spring at an advance of \$1.00 to \$1.50 a hundred above the market price for ordinary sorts. Hyacinths are being brought on for Easter from bulbs of extra quality ordered direct from Holland. Most of these are still in frames, where they have wintered since October, and are gradually coming into flower. Many are in twelve-inch pans holding a dozen bulbs. In their selected list Gertrude and Charles Dickens were the best deep pink, and Gigantea a beautiful light pink. The best yellow was Ida; La Grandesse was the choice among white ones, with the old Baroness Van Thuill also superior. Czar Peter was the best light blue, and beds of King of the Blue and Leonidas were showy masses of an intensely deep shade of the same color. These are all single-flowering. All this stock is already sold, with only the responsibility to the grower of having it at the best flowering stage for Easter. Altogether, 4,000 square feet of glass are used here for hot-beds, and seven houses 100 feet long. Some large plants of *Acacia paradoxa*, eighty years old, were coming into flower for Easter, valued at \$15.00 each, wholesale. Lilies were also being brought on, and a large stock of medium size and standard Azaleas, besides *Cytisus Canariensis* and small bushy plants of *Deutzia gracilis*. In a house of foliage plants young specimens of *Livistonia rotundifolia* looked well, as did *Phyllanthus roseopictus*, with variegated bright pink foliage; the latter is said to thrive well outside and is especially useful for summer planting. Tall plants of the New Zealand Flax *Phormium tenax*, the comparatively new *Dracæna Sanderanæ*, and *Begonia corallina*, probably the best of the older Begonias, and almost continuously in bloom, were also noted. Several old standard plants of the Niphetos Rose which bloom when other white roses are scarce, afforded flowers which have a demand for funeral work. But the specialty here is the Otaheite Orange. One of the houses was filled with plants, now a mass of fragrant bloom, the busy hum of bees adding to the summery effect. On some plants the tiny oranges were just formed, and all will be brought into ripened fruit for Christmas. The plants were grown from cuttings made in February two years ago, and a few specimens left over from last year's stock still show large handsome fruit. Standards are grown a year longer than the specimen plants. During the two years of growth the fruit is cut off each season as soon as it is formed and the plants are trimmed into shape. They are planted out in summer in partial shade. The fruit persists for eighteen months under ordinary conditions with proper watering. The plants seen here were compact and shapely and in perfect health,

At Louis Schmutz's place on Clarkson Street were two houses of Hydrangeas, some of them far enough along to be kept cool now, with the advantage of hardening off and thus lasting longer in the purchaser's hands. Plants of Azaleas and *Deutzia gracilis* were also held in check. Among odd specimens collected during a long business course were old-fashioned plants of Myrtle, popular for making wreaths for German weddings; an old *Maréchal Niel* Rose, trained to a trellis and in luxuriant bloom; the flowers sell for \$3.00 a dozen, wholesale. One of the ten houses contained tall old Camellias, some of the larger ones crowded to the peak of the roof, fifteen feet above. Two of these venerable trees were covered with flowers and buds, and time's mockery was illustrated in the changed fortune of these once fashionable and costly flowers which now find sale only on the Bowery, for funerals. In this house was also a sturdy plant of *Daphne odora*, left over from the years when these plants were found in every Camellia-house, and a standard *Acacia pubescens*, twenty-five years old, which measured eighteen inches at the base of a trunk of almost that circumference for five feet, when it divided into branches under which one could stand, with room to spare. The flower-sprays of this tree-like standard had been cut recently, but the grace of its form and foliage still remained. There were showy plants of the tender *Streptosolon Jamesoni*, with drooping sprays of rich orange nasturtium-like flowers, *Swainsonia*, and sturdy well-grown English Primroses and Daisies in frames. Three hundred plants of Crimson Rambler Rose are being forced here for Easter and for Memorial Day. Two-year-old plants, wintered out-of-doors under glass, were brought into heat two months ago. They are in six-inch pots and trained to an arch two feet high. This Rose breaks earlier than any other, and the plants seen here last week carried large clusters of tiny buds with the pink just beginning to show. They are already engaged at \$18.00 a dozen, wholesale.

On the same thoroughfare Charles E. Koch has twenty-seven houses, besides 300 sash in frames. In a large variety of bedding plants were 30,000 Geraniums, half of which were the brilliant double General Grant. Even this large stock is but a small part of the Geraniums used in the cemeteries in this district. Eight houses of Carnations supply cut flowers, and 1,000 to 1,200 blooms of Lizzie McGowan alone were cut on some days last winter, and 2,400 spikes of Mignonette were part of the Easter stock last year, when this movable feast came earlier.

George E. Bennett, successor to William Bennett, among the pioneers in this business in Flatbush thirty-two years ago, has fifteen houses devoted entirely to Carnations and Mignonette. Besides the usual market varieties of Carnations, Mr. Bennett has a promising sport from Daybreak. About 1,800 Carnations are marketed daily now, and as many as 6,000 a day during the midwinter holidays.

In a line with the other establishments on Clarkson Street is that of Mrs. Meissner, and here fourteen houses were taken up with Easter stock and bedding plants, all of which had found ready buyers. Two thousand five hundred pots of Lilies, equally divided between *L. Harrisii* and *L. longiflorum*, thirty small plants of *Hydrangea Otaksa* and of Azalea, were among the Easter stock. Small plants of *Pteris densa compacta*, grown from spores, made a stretch of beautiful bright green. Here, as elsewhere, plants of the Bermuda Lily contrasted unfavorably this season with those of *Lilium longiflorum*. The complaint is general that the Bermuda bulbs are each year less satisfactory; that they are not properly ripened, the tops being cut while yet green. Lack of proper cultivation of the bulbs is also alleged to account for their inferior quality. While many of the *Lilium Harrisii* from Bermuda show defective and worthless buds and spotted foliage, it is quite common for a bulb of *L. longiflorum* to have two and even three and four stalks, with abundant buds.

Of the five acres of the Messrs. Dailedouze Brothers, 45,000 square feet of ground is covered with glass. Carnations occupy three-fourths of the twenty-four houses, several being in use for the exceptionally large strain of Mignonette grown by this firm, and which has a place all its own in the New York trade. The end of the season is approaching, although there will be cuttings until the middle of June. Closely flowered spikes having a diameter of two to two and a half inches for six inches and more are typical of this strain. With no special preparations for Easter, these houses were none the less interesting, with large collections of all the best Carnations grown to perfection. The selling qualities of William Scott are shown in the fact that one-third of all the Carnations grown are of this variety; Lizzie McGowan ranks next in popularity, with Daybreak third. These bring an equal price, while smaller quantities of the variegated Helen Keller and Minnie Cook, the

light yellow Eldorado and the scarlet Hector bring one-third more. Of the regular sorts as grown here Meteor is found to be too single, and the blooming season of three months in midwinter is too short. A good crimson seedling is needed to supersede it. John Burton's new white Carnation is here, a perfectly clear white, the petals cup-shaped and shorter than those of Lizzie McGowan, flowers of medium size, with a good stem. They are almost camellia-like in their whiteness and regularity of form. Alaska has also done well here. Helen Keller is particularly successful here, owing to the soil, Mr. Dailedouze thinks, and perhaps nine-tenths of the carnations sold in New York come from these houses. Minnie Cook they find apt to burst in the calyx. Eldorado flowers fairly well, though not freely, and is a good keeper. The clear light yellow petals, which are deeply serrated and delicately touched on the edges with rosy pink, suggest the flowers of Andalusia, a variety introduced from France seven or eight years ago and discarded in a few years as not free-blooming. The even distribution of the petals of this very full Carnation helps to make a pleasing flower, and its color is charming. Bouton d'Or has proved satisfactory here, but Buttercup is too shy during winter, though it is said to be entirely satisfactory in this respect in some parts of Connecticut. Eldorado is said to do well out-of-doors, and also to flower well under glass in summer, as do William Scott and Lizzie McGowan, while Daybreak is not so good in summer, Minnie Cook only fair, and Helen Keller does not flower at all. Among new carnations being tested are a silver-pink seedling not yet named, and known as No. 3. The light outer petals shade deeper to the centre and the flower has a spicy fragrance. The calyx, stem and other characteristics are altogether superior, and its uniform good qualities won a certificate of 100 points from the American Institute recently. A new deep rich crimson under trial promises to make good the weak points of Meteor in flowering early and late in the season. Cuttings made at Christmas for next season's flowers will be planted out from the middle of April to the first of May, and brought in late in August. Flowers are cut from September until July, 1,000 to 2,000 a day now, and for Christmas and New Year's, when they can be held on the plants for a week or two, from 8,000 to 10,000 every twenty-four hours. They are allowed to develop freely before cutting, but not to be overgrown, and are kept cool twelve to eighteen hours before delivering to buyers. The propagation of Chrysanthemums for cut flowers is just begun.

The adjoining houses belong to Joseph Gard, who, fresh from a wide experience in Switzerland and France, in 1862 established a nursery of twenty-five acres of trees and shrubs on this site in partnership with the elder Dailedouze and Zeller. After the dissolution of the firm and division of the ground, Mr. Gard adapted his business to trade demands, and for many years grew Marie Louise Violets with marked success. His output some years ago averaged 16,000 a week, and \$3.00 a hundred was the uniform price paid him for all his stock throughout one season. Later, \$2.50 was obtained from November until New Year's, when the price fell to \$1.25, and in March to sixty cents. Within the past four years Violets have done indifferently here, and Mr. Gard notes a similar want of success with Roses in Flatbush, owing, he thinks, to changed atmospheric conditions. He states that he used to gather Tea Roses by the bushel out-of-doors in summer, and now these plants do not flourish at all. Bedding plants are the main crop here, and Verbenas a specialty, 25,000 of these plants being sold during spring.

Returning to the heart of the town by way of Lenox Road, Mr. G. Messeberg's place may be visited, established twenty-nine years ago by the father of the present owner. Thirteen well-kept houses, besides many frames, were filled with Easter and bedding plants. The Longiflorum Lilies grown here this year are from Japanese bulbs, and the experience of Mr. Messeberg shows that these produce more and better flowers than the same sized bulbs of *L. longiflorum* from Bermuda, and he thinks it is only a question of time when Bermuda bulbs will be discarded. He considers *L. longiflorum* superior to *L. Harrisii* for a late Easter, as the flowers have more substance and keep longer, and are, besides, more graceful, while a few hot days wilt *Lilium Harrisii*. Bulbs of the latter from Bermuda cost Mr. Messeberg \$20.00 a thousand, and those of *L. longiflorum*, from Japan, \$38.00. But these more costly ones can be depended upon for a full and healthy crop, and the flowers sell for two cents apiece more at wholesale. Hydrangeas, Cinerarias and the best standard sorts of Azaleas filled several houses. The best red Azalea was Madame Van der Cruyssen, the richly colored flowers having fluted edges; the double *Vervæneana* and the single *Comte de Chambord* were the best pink; Bernard André alba and Raphael were among

choice white kinds, with Baroness de Weir best of all. Self colors of pink and white are most in favor. An entire house is filled with the best varieties of English Pelargoniums, and the new Souvenir du President Carnot Rose is grown in large numbers. The crop of 35,000 Pansies is already sold.

In the houses of C. Wocker, just beyond, were forced plants of *Deutzia gracilis* and superbly flowered Hydrangeas, many of the heads more than a foot across. There were plants of the showy *Metrosideros* and the uncommon and beautiful *Choisya ternata*, with orange-like flowers, and the deep green foliage almost equally fragrant.

New York.

M. B. C.

### Notes.

The Civil Service Commission of New York city will hold an examination for the position of gardener and gardener's apprentice, at its office on the corner of Centre and Franklin Streets, at ten o'clock in the morning of April 22d. Applications may be addressed to S. William Briscoe, Secretary, New Criminal Court Building, New York city. Candidates must be citizens of the United States, and candidates for the position of gardener's apprentice must be between the ages of eighteen and twenty-one years.

We learn from a correspondent in Copenhagen that the ladies of that city last month collected an interesting exhibition of Orchids in flower as well as paintings and engravings of the native Orchids of Denmark, and of exotic species, besides pottery decorated with Orchid designs. The exhibition was most successful and attracted large numbers of visitors, including the entire royal family. The aim of the undertaking was to raise money to help the construction of a building in Copenhagen for the exhibition of work exclusively by women.

Professor D. T. MacDougal writes to *Science* that the project for establishing a botanical laboratory in the American tropics has made such progress that a commission has been organized for the selection of a site for the proposed laboratory and for ascertaining how far the cooperation of American and British botanists can be enlisted in the scheme. The commission will select a location conveniently placed with reference to towns or settlements and in easy connection with a marine substation, and yet near the presence of a body of undisturbed tropical vegetation. The American members of the commission are Professor Douglas Campbell, of Stanford University; Professor J. M. Coulter, University of Chicago; Professor W. G. Farlow, Harvard University; Professor D. T. MacDougal, University of Minnesota. The committee will be ready to make an informal report to the American Association at Detroit, and the British Association at Toronto, at their meetings in August.

In Bulletin No. 9, which discusses the rate of increase in the cut-over timber lands of Minnesota, we find, among miscellaneous notes, that the oldest White Pine noticed by Mr. H. B. Ayres had 348 rings on the stump and a diameter of thirty inches. The top of this tree was broken off at 114 feet above the stump and sixty-eight lineal feet of log timber were taken from it which scaled 1,400 feet, board measure. A larger tree than this, although one not as old, was forty-eight inches in diameter on the stump and contained 4,050 feet, board measure, of log timber. This tree with several large ones near by which grew on fertile soil averaged about 253 years old when cut. When fifty years old they average only eight inches in diameter, but at 150 years of age they were adding about half an inch to their trunk diameter every year. The largest Norway Pine noticed was 330 years old with a stump diameter of thirty-two inches and a height of 103 feet. Seventy-two lineal feet of log timber taken from it scaled 1,830 feet, board measure.

Ordinary Barn-yard Grass, *Panicum Crus-galli*, is a coarse annual, occurring in damp places or cultivated ground, and often becomes a troublesome weed. Among three kinds of Millet recently received by the Massachusetts Experiment Station is a variety of this Barn-yard Grass which seems to be botanically identical with our plant, although it differs from it somewhat in its habit of growth. Professor Brooks, of the Massachusetts Station, recommends it enthusiastically as a fodder crop for feeding green or for the silo, and says that it may yield ten or twelve tons of fodder to the acre, or if thinly sown in rows a foot apart it will produce from fifty to ninety bushels of seed. In a newspaper slip lately issued by the Maine Experiment Station it is said that while this may be a valuable acquisition, farmers ought to be cautioned about procuring the seed which is sold as Japanese Millet. Certainly the

seed of our *P. Crus-galli* should only be purchased of dealers who will be sure to furnish the seed of the Japanese variety, since the mischief which would be wrought by sowing the seed of the ordinary Barn-yard Grass is self-evident.

Mr. F. W. Burbidge read an interesting paper at Manchester last month on the "Culture of Hardy Bulbs in England." He stated that England paid half a million dollars every year to Dutch bulb growers in spite of the fact that it had been proved that the home supply of Narcissi, Crocuses, Tulips and others could be easily grown in favored parts of England, and with special care in the market-gardens about London and the Isle of Wight, where they would be the most profitable of crops. Even in Holland and other places where bulbs have long been specially cultivated success is only assured on plots with a suitable soil, and that such soils can be found at home is proved by the fact that hundreds of acres are already in cultivation both in Great Britain and Ireland. The thing to be remembered is that the soil which grows the best Hyacinths is not the best for Narcissi nor for Tulips; and, again, land however good will not grow bulbs year after year without enrichment or recuperative crop rotation. In fact, Mr. Burbidge said that it was not soil or climate in Holland which made that country preëminent for good bulbs, but it was the methodical thrift and skillful industry of the people.

The discovery that the pith of the corn stalk can be used in the construction of war vessels is likely to be of benefit to agriculture in more than one way. The chief use of this pith is for a packing between the inner and outer shells of the vessel so that when pierced by a projectile it will absorb water and swell so rapidly as to close the opening before the vessel leaks to a dangerous extent. Experiments with this pith have been so satisfactory that it has been adopted in the construction of all our new vessels of war, and European nations have commissions for investigating the same material, so that the use of corn pith will make a market for what was once a waste product. In the process of extracting this pith the blades and husks are removed and the stalks are cut into small pieces. When the pith is taken out from this stalk the remainder is ground up into a flour-like substance which resembles bran. Some experiments with this "new corn product," as it is called, have been made at the Maryland Station with the remarkable result that it is found to contain eleven per cent. more of digestible matter and two per cent. more of digestible protein than the whole fodder does when shredded. It contains as much digestible matter as the corn blades and more total digestible matter and half of one per cent. more protein than Timothy hay. It does not contain as much digestible albuminoids as wheat bran, but it equals that food in the total amount of digestible matter. It keeps as well as bran or cottonseed meal. It is in such condition that it can be uniformly mixed with any ground grain, and when used as a base it is possible to make a complete and normal ration for stock in one bulk without the necessity of feeding grain and hay separately. Animals fed upon such a ration eat it with relish, and keep in normal condition. Since there is only one pound of pith to fourteen pounds of blades, husk and stalk, this new material amounts to a very considerable portion of the fodder.

Dr. Robert Hogg, the eminent pomologist and writer on various horticultural subjects, died on the 14th of March, in London, at the age of seventy-nine years. Dr. Hogg was a graduate of the University of Edinburgh. Being devoted to the study of natural science, and especially of botany, he acquired the knowledge of practical horticulture, and soon developed a taste for pomology, which enabled him later on to prepare the valuable *Fruit Manual*, a standard descriptive work. He began the publication of a larger work on British pomology, but only one volume, which treated on the Apple, was published. Dr. Hogg was a voluminous writer on various horticultural subjects, was for many years the editor of the *Journal of Horticulture*, a conspicuous member of the Pomological Society and Secretary of the Fruit Committee of the Royal Horticultural Society.

Philip Wickens, who for forty years was connected with the nursery firm of Ellwanger & Barry, died at Rochester on the 29th of March, in the sixty-ninth year of his age. He was born at Rotherfield, Sussex, England, and came to this country in 1851, where he soon became an authority on hardy fruits. He was an expert in many other branches of horticulture, a born gardener and an enthusiastic and discriminating lover of natural beauty. He was a retiring man, devoted to his special work, but of a genial sunny temper, which helped to brighten the lives of his associates.

## GARDEN AND FOREST.

PUBLISHED WEEKLY BY

THE GARDEN AND FOREST PUBLISHING CO.

OFFICE: TRIBUNE BUILDING, NEW YORK.

Conducted by . . . . . Professor C. S. SARGENT.

ENTERED AS SECOND-CLASS MATTER AT THE POST-OFFICE AT NEW YORK, N. Y.

NEW YORK, WEDNESDAY, APRIL 14, 1897.

## The National Forest Reservations.

CERTAIN western Senators are strenuously demanding the revocation of Mr. Cleveland's proclamation on the 22d of February, which established the great forest reserves on the Government lands. It is not likely that they will fully succeed, but some amendments to the Civil Sundries Bill are now before the Senate as a sort of compromise. The excuse is offered for attempting to legislate in such an unusual way that the wants of miners and settlers are immediate—that they need firewood and fencing and the right to build roads to their mines. This is true, but no one is suffering, and the fact is that the property of no one except the Government is threatened. Beyond question, some way of adjusting the rights of individuals and of the Government must be devised, but it is notorious that every effort to protect the public domain in these transactions by the agents hitherto appointed by the Secretary of the Interior has failed. Our defective land laws, inadequately and insufficiently enforced, have produced the inevitable result of making the inhabitants of the public-land states and territories look on the public domain as their own personal property. Few men in the west consider that they do wrong in cutting timber or pasturing their domestic animals on public land, and any attempt to check them is considered an infringement of their vested rights. At present there is but one way in which the reservations can be protected from fire and theft, and that is by military control. Of course, the troops should not be used permanently, and what is needed is the authority from Congress for the Secretary to organize a quasi military service of permanent trained forest officers to protect the reservations and carry out such rules and regulations as he may make for their administration.

A year ago the Secretary of the Interior, appreciating the gravity of the situation, and desiring more information than he possessed on the general forest situation in the west, asked the National Academy of Sciences for advice in the matter. A committee of experts was appointed by the Academy to consider the whole question, and during the past year it has devoted itself assiduously to this work. The report and recommendations will be in the hands of the Government in a few days,

and it seems at least unwise to legislate on such an important question before the information collected by the highest scientific body in the United States and the scientific adviser of the Government can be utilized. The legislation proposed by this committee, together with the report accompanying it, will be before Congress early next month, and in order to inform the Secretary of the Interior of its leading features the committee addressed to him on the 5th of April a letter, which we publish entire as a matter of record, and to show how carefully the rights and privileges of actual settlers have been considered:

To the Honorable

The Secretary of the Interior, Washington, D. C.

Sir,—The legislation relating to reserved forest lands of the public domain which the Commission of the National Academy will recommend in its final report, now in course of preparation, provides for the following:

First, that authority be given to the Secretary of War to make details of troops, at the request of the Secretary of the Interior, to protect temporarily, and until a forest service is organized, the property of the Government in the forest reservations from fire and trespass, and to enforce such rules and regulations as he may make for their care.

Second, the establishment of a permanent Forest Bureau in the Department of the Interior, composed of trained officers, to administer, maintain and improve the reserved forest lands.

Third, the appointment of a Commission to institute as rapidly as possible, under the supervision of the director of the Geological Survey, topographical surveys of the reservations and determine what portions of them should be permanently reserved on account of their forest covering and what portions should be reopened to entry and sale.

Fourth, to authorize the Secretary of the Interior to issue the necessary rules and regulations for the protection, growth and improvement of the forests on the reservations, for the sale of timber, firewood and fencing from them to actual settlers in and adjacent to the reservations and to owners of mines legally located therein for use in such mines; for granting permits to sawmill owners to enter the reservations for the purpose of manufacturing such lumber as may be sold to actual settlers in and adjacent to the reservations and to the owners of mines located therein; for allowing actual settlers who have no timber on their own claims to take from the reservations firewood, posts, poles and fencing material necessary for their immediate personal use; for allowing the public to enter and cross the reservations; for granting to county commissioners rights of way for wagon roads in and across the reservations; for granting rights of way for irrigating ditches, flumes and pipes, and for reservoir sites; and for permitting prospectors under such rules and regulations as he may from time to time establish to enter the reservations in search of valuable minerals.

The Commission will recommend that the reservations be opened to the location of mining claims under the general mineral laws, and that the owners of valid mining locations in the reservations made and held in good faith shall be permitted to fell and remove from their claims the timber growing on them for actual mining purposes in connection with the particular claim from which the timber is cut. It will also recommend that the owners of unperfected bona fide claims or patents of land included in the forest reservations shall be permitted to relinquish their claims to the Government, selecting in lieu tracts of vacant land open to settlement, but not exceeding in area the tracts covered by their claims or patents; and that the owners of such unperfected claims shall not be subjected to additional charges for entries or record, and that credit shall be allowed them for the time spent on the relinquished claims. The Commission will also recommend that the Secretary of the Interior be authorized to enter into negotiations with the land-grant railroad companies for the purpose of concluding agreements by which these companies may relinquish

to the United States the title acquired by them to lands within their granted and indemnity limits when these lands lie within the boundaries of forest reservations, and may accept other unappropriated lands in exchange from the even-numbered sections within their granted and indemnity limits not included in forest reservations.

Very respectfully,  
your obedient servants,

(Signed) C. S. SARGENT,

W. H. BREWER,  
ARNOLD HAGUE,  
GIFFORD PINCHOT.

### The Red Cedar.

THE Red Cedar is a familiar tree to almost every American, since it ranges from Cape Cod to Vancouver's Island and from Canada to Florida. At the north it is found on uplands, cold, dry and hungry, while in Florida it inhabits swamps which are covered with water for a considerable portion of the year. In the deep bottomlands of Arkansas and Texas it is a noble tree, sometimes a hundred feet high, with an irregular trunk buttressed at the base and often four or five feet through. In the fertile valleys of the middle Atlantic states, when it has opportunity for full development, it is a broad-topped and dignified tree, while on the low limestone hills of northern Alabama and the neighboring states it is small and bushy, and on dry ridges, both in the west and in the east, it is little more than a shrub, and often fairly prostrate. The habit of the tree varies as much as its size, and one who is accustomed to see its pyramidal form with sharp spire-like top would hardly recognize it on the seacoast with its short, stout trunk and stiff horizontal branches which have developed under the stress of Atlantic gales. This wide variety means that it adapts itself to all sorts of surroundings and that it can live almost anywhere throughout an immense geographical range.

It need hardly be stated that the Red Cedar is really not in any botanical sense a Cedar, but a Juniper (*Juniperus Virginiana*), one of ten species found in the United States. Besides these there are from twenty to twenty-five other Junipers in the northern hemisphere, scattered from the arctic circle to the highlands of Mexico and the West Indies in the New World, and to Africa and southern Japan in the Old World. Of the American species the Ground Cedar, or common Juniper, crosses the continent from Greenland to Alaska and extends through northern and central Asia and Europe, so that it is altogether the mostly widely distributed tree in the northern hemisphere. Many garden forms of this species are known in cultivation, some dwarf, some with colored foliage, some of compact habit, some columnar, and others with pendulous branches. Among these a fastigiate form, called in nurseries the Swedish Juniper, is the best known in the gardens of this country. Another Juniper is confined to Texas and portions of Mexico, and there are half a dozen more which belong to the Pacific side of the continent and the forests of the Rocky Mountains. The Red Cedar is the largest and most useful of all the American Junipers. In some of the swamps of western Florida and in certain other places in the south its wood is formed with a singularly straight grain, which is soft and easily worked, and so completely adapted to the requirements of lead pencils that it is almost exclusively used in their manufacture. Its fragrant odor is repellent to moths, so that cedar-lined chests and closets are in universal use for storing woollens. It is so durable in connection with the ground that it is the best tree we have for fence-posts or the sills of buildings, and its rich color, its durability and its pleasant fragrance make it useful in many kinds of cabinet-work. But while its economical value has been always understood, its use in horticulture has been comparatively limited. Large quantities of these trees were raised some years ago for hedge-plants in the west,

but they did not prove acceptable for this purpose. This was not only because the Red Cedar grows slowly, but the branches of the tree have a habit of dying when they come in contact with those of another tree, so that it is not as good for this purpose as the *Arbor Vitæ*. It endures shearing quite as well as any other tree, however, and since there seems to be a tendency now to try the fashion of formal gardens in the northern states, there is no tree so well adapted to take the place filled by the Cypress in the gardens and southern Europe. But, even if it is not mutilated in this way, the tree in any of its forms fits naturally into an American landscape. When grown in rich soil, with an opportunity to expand, in a sheltered place it will make a dignified and stately specimen, and where a cylindrical or spire-topped tree is needed nothing better than the Red Cedar can be found.

The natural form of these trees on a cold New England slope is seen in the picture on page 145, which represents them as every one knows them in a winter landscape at the north. Here is the perfection of careless grouping and a grace of individual form which the duller eye can at once perceive. Why a more extended use has not been made of the Red Cedar in park planting is difficult to understand, since it would be invaluable in certain positions. It is objected to the tree in winter that the foliage turns to a dull brown, but really the bronze color is in perfect accord with the tone of the whole landscape. The cheerful green of certain conifers is effective, too, under certain conditions, but in very cold weather the leaves of most species turn dark, and, indeed, any light green seems out of place in a season when there is no growth in vegetation. We associate the green with active life; it is the color of spring and summer, and we naturally expect that trees with persistent leaves will show in some way that they are in a state of suspended animation. There has been so little demand for Red Cedars that nurserymen do not keep them in large quantities, although they are very easy to raise from seed. There is little difficulty, however, in transplanting young trees from old pastures, where they spring up from the seeds dropped by birds. These long lines of Red Cedars along fence rows are conspicuous features in the landscape of the older settled parts of the country, and their effectiveness in such situations and upon the slopes of rocky hills and on the summits of knolls ought to convince every one of their usefulness in planting parks and private grounds large and small.

### Mature White Pine in Pennsylvania.

TRACTS of uncut White Pine in Pennsylvania are few in number and of restricted area. It is doubtful if there are in the state to-day half a dozen tracts of 2,000 acres in extent in which the White Pine occurs in sufficient quantity to give character to the forest. One of the best of the large tracts is the property of Mr. John Du Bois, and is located near the town of that name in the north-western part of Clearfield County. There remain here about 1,500 acres of uncut Pine, but the merchantable timber of all sorts is being systematically harvested. The Pine, as is the case in all the mature timber of the state, occurs as scattered individual trees in a mixed growth of Hemlocks and hardwoods. In some places Hemlocks are entirely absent, while again they are the prevailing trees. So, too, within the space of half a mile one may find a heavy stand of Pines and an area where few of the trees occur.

The yields of two acres were measured in the Du Bois tract and illustrate this varying stand of Pine. The two sample acres were less than a mile apart, and in general the character of soil and moisture supply were similar—a clay loam overlying laminated shale, well-watered by little brooks which led into Narrow Creek. In both areas the Pines were the tallest trees, with a second story of Hemlocks having a slight admixture of hardwoods.

In one acre there were 37 White Pines, ranging in diameter, at breast-high, from fifteen to forty-five inches; 84

Hemlocks, more than six inches in diameter, and 179 smaller Hemlocks; 11 Beech and Red Maple more than six inches in diameter, with 221 smaller hardwood trees. In addition to the small Beech, Maple and Birch trees, there were Dogwoods, Cucumber-trees, a few masses of Laurel, etc., making a moderately dense undergrowth. The other acre had a much more open and irregular stand, with scanty undergrowth of hardwoods and shrubs. It contained 23 White Pines of the same size as those in the first acre, 37 Hemlocks, and 74 hardwoods (Beech, Maples and Birches) over three inches in diameter. The first of these two sample areas contained Pine of the finest quality and size. It was found to range in age from 230 to 260 years. Seventeen of the largest Pines were carefully measured after being cut into logs, and contained above 40,000 feet, board measure, the largest tree measuring more than 4,300 feet, board measure. The average length of trunk to base of crown in thirty trees was 91 feet, the longest trunk free of limbs being 112 feet, while the tallest tree on the acre was 158 feet high. The total contents of thirty of the trees on this acre was found, by Scribner's rule, to be above 60,000 feet, board measure.

Many single acres could be found equal to the one here cited, though it is much above the average yield of the entire tract. The White Pine in this particular locality is tall and straight, with comparatively short crown. In much the greater part of the tract the Hemlock is the prevailing tree, and in the limited areas where the hardwoods predominate the White Pine is of less frequent occurrence, with greater crown development, thus giving a relatively smaller yield of the best timber.

Charles A. Keffer.

#### Burdock as a Vegetable.

THE well-known definition of a weed by Emerson as "a plant whose virtues have not yet been discovered," is confirmed by the better agricultural authority of Schwerz, according to whom "a weed is a plant of which the direct uses are unknown to man." Both the poet-philosopher and the scientific farmer implicitly admit, I think, that as man brings more and more of nature under his control—in other words, as he brings more and more plants under cultivation, many of them, hitherto scorned as weeds, must cease to be considered as such. I have often seen ridiculed the Chinese custom of eating birds' nests, bears' claws and other incomprehensible delicacies, but I cannot help admiring the power of pantophagy on the one hand and the refinement of culinary skill on the other, which can convert into means of human enjoyment things apparently worthless and revolting. If, as philosophers say, civilization consists mainly in bringing natural forces under man's subjection, China must be given a high place in the scale of civilization from a culinary point of view.

Is it not a real triumph of art to extract food for man from so coarse and ugly a weed as Burdock? Most books on botany in the English tongue describe Burdock, *Lappa major* or *officinalis*, as a pestiferous weed, and many an agricultural bulletin gives careful instruction how to destroy it. Perhaps the only use that has been made of *Lappa* in America is for medicine. The root contains a bitter principle, a resin and tannin, and it is said to have an aperient and diuretic effect. It also has some reputation as an alterative in constitutional blood diseases, and the readers of GARDEN AND FOREST may have used the so-called "Burdock tea." In Germany, where the three species, *L. major*, *L. minor*, *L. tomentosa*, are widely spread, they were formerly much used as medicines under the name *Radix Bardanæ*; and they are even now regarded by some as good blood purifiers. Perhaps from the burr of the seeds the plant has the repute of power to stimulate a rich growth of hair, and an extract for this purpose is made from the roots. The peasants of the south of England use the roots as an antiscorbutic, and the leaves are employed in making a green elder ointment for the use of farriers.

All these medicinal uses are not to be despised, but they are unimportant when compared to the value of the plant as an edible vegetable; since the kitchen is more important than the drug store, the cook is nearer our hearts than the apothecary. Even in England the alimentary value of Burdock was not always despised. Sowerby writes in his *Useful Plants of Great Britain*, "The stalks of the Burdock, cut before the flowers open and stripped of their rind, form a delicate vegetable when boiled, similar in flavor to asparagus. In the raw state they may be eaten with oil and vinegar as salad. They were sometimes candied with sugar in the time of Bryant, as those of Angelica are. They are slightly laxative, but are perfectly wholesome. The roots of the plant are mildly diuretic and diaphoretic, and have been used with advantage in gout, rheumatism and calculous complaints. The decoction of the root is generally employed, but the seeds and leaves possess nearly the same properties, though the latter are slightly purgative. The bruised leaves are applied by the peasantry in some districts, in cataplasms to the feet, as a remedy for hysterical disorders."

In Japan, Burdock grows wild in several places, but it is also extensively cultivated as a vegetable. Every one knows and eats "Gobo," the usual appellation for this plant, although a more refined and almost obsolete name is "Kitakisu"; sometimes it is called "Uma (horse)-fuki (*Nardosmia*). It is familiar to the Ainu under the name of "Seta (dog)-korokoni (*Nardosmia*). Both the Ainu and the Japanese prefixes, "seta" and "uma," when applied to plants, seem to have much the same sense as the English "dog," in dogwood, dogbane, etc., and the "horse" in horse-radish, horse-chestnut, horse-mint, etc. The Ainu use it as food as well as medicine. They boil the tender shoots with beans, and the roots are put into soup. For medicinal uses the young leaves are softened by rolling them between the palms, and applied to skin eruptions. The Japanese esteem *Lappa* for similar purposes. It is used in many preparations for its medicinal properties, which, they believe—at least, the old-fashioned empirics believe—consist in counteracting the action of some kinds of poisons. Grated and made into pulp, the roots are applied as a poultice in eruptions of the skin. But by far the more important use is made in the kitchen. As regards this plant we have outstripped the pantophagous Chinese, for they have not raised the plant to the dignity of a market vegetable. "When young," says a Chinese book on botany, "the tender leaves of the *Lappa* are cut and eaten as greens; the roots may be boiled or steamed and eaten, but people nowadays rarely use the plant." Among the Japanese, however, it has been under cultivation for years, and possibly for centuries. It enters the kitchen of every household, not being ostracized from the menu of the most high-toned restaurant. Thousands of acres are devoted to its culture. Official statistics for 1888 give the total production of *Lappa* in the country at about seventy-two million pounds, valued at 422,134 yen. The roots average 350 grains in weight.

The production of so large a quantity is not at all to be wondered at when we recollect that *Lappa* ranks high in the scale of nutritive plants. In the amount of nitrogen it stands higher than potatoes, beets, carrots or turnips; in fact, few roots or tubers approach it. I append here its chemical composition, as compared with some other commonly used vegetables:

	H <sub>2</sub> O	N.	Ash.	K <sub>2</sub> O	Na <sub>2</sub> O	CaO	MgO	P <sub>2</sub> O <sub>5</sub>	SO <sub>3</sub>	SiO <sub>2</sub>	Cl.
Potatoes.....	750	3.4	9.5	5.8	0.3	0.3	0.5	1.6	0.6	0.2	0.3
Sugar beets....	815	1.6	7.1	3.8	0.6	0.4	0.6	0.9	0.3	0.2	0.3
Turnips.....	920	1.8	6.4	2.9	0.6	0.7	0.2	0.8	0.7	0.1	0.3
Carrots.....	850	2.2	8.2	3.0	1.7	0.9	0.4	1.1	0.5	0.2	0.4
Burdock.....	738	5.6	10.5	4.3	0.2	1.1	2.0	0.9	0.7	0.1	..

So important a crop as Burdock has, of course, many varieties developed, but the best known among them are few in number. They are usually named from the localities where they were first developed or where they thrive

best. A variety known as the Takinozawa, raised chiefly near Tōkyō, has a slender root, about four feet long, and is of very fine quality. In the vegetable market of Tōkyō it commands a respectable price. The Owura variety, so named from a small place in the province of Shimosa, where they produce only about two thousand roots a year, attains the huge size of one and a half feet in circumference and two and a half feet in length; this kind is sold at the rate of about twenty sen (a sen being a hundredth part of a Japanese dollar) apiece. In its form this variety is like the beet. The two kinds most popular in the markets of Kyoto are the Yamato and the Horikawa; in fact, these seem to be only different names of the same variety.

In raising Lappa much attention is naturally devoted to the right selection of the soil. It is a common belief among cultivators that a light sandy soil is specially adapted to it, and it is true that roots grown from such soil are long and slender, but they are prone to be hollow at the centre and rather tough at the rind. A stronger and deeper soil, say clayey loam, seems to impart firmness to the root and a better flavor. To gain the most satisfactory results, the soil must be plowed deep and finely pulverized, or else an undue amount of labor will be required in harvesting the roots. Indeed, digging Burdock is a proverbially hard task; it has become almost a fine art to do it well. Many an old writer recommends digging the soil to the depth of some four or five feet, and then putting in green leaves, stalks, turf, and so forth, in a layer of a foot deep, and covering that with the earth that was excavated. The surface must then be well hoed in both directions. So much care, however, is only necessary when exceptionally fine specimens, for show or otherwise, are aimed at. One peculiarity of Lappa is that it is not adapted to rotation—that is, it thrives better if planted continuously on the same soil; in new land the roots are likely to become forked. It is also grateful for good manures—compost, night-soil, and especially to rice-bran—but if compost is applied it must be well decomposed, or else the roots will throw off too many branches.

When the soil is properly prepared seeds are planted in rows three feet apart, five or six seeds being placed every six to eight inches in a row. In Owura, the usual time for sowing is the early part of May or late in April. Before the early part of June the young plants are thinned out, leaving but one in the hill. Very often liquid manure is applied two or three times before the roots are harvested late in December. Another method is to plant the seeds in August, so as to have the vegetable ready for spring use, in which case they are sown more closely, since they do not grow as vigorously as those planted in spring. Lappa is a slow grower and takes over two hundred and twenty days to mature. Seeds retain their vitality for five years, and many a gardener asserts that the best crop is obtained from those three years old. They say that new seeds produce roots which throw off too many branches and flower-stalks. This statement, however, is not always verified. For keeping and marketing, the vegetable may simply be left where it was grown or kept buried in the earth like beets or turnips.

I am aware that a discourse on Burdock will be of little interest to Americans unless it contains some information regarding the mode of using it, but it must be remembered that Japanese cuisine differs widely from the American. I need only state in general terms that, after their skin is scraped or peeled off, the roots may be sliced into long strips or cut into pieces of less than an inch in length, and boiled with soy, salt or Spanish pepper, to impart savor to them; or, if boiled alone, they may afterward be browned in sesame oil, which of itself will flavor them. Another common way of cooking them is to scrape off the outer skin and cut them into pieces about two inches long, then, when they are boiled soft, to take them out of the pan and mash them; then make them into cakes, much as you treat oyster-plants. A kind of salad, though not uncooked, is also made of them. A rather unique and more elegant

process consists in stuffing the roots with sea-eel, and boiling them, after dipping them in a preparation containing soy and pepper. Slices of lappa fried and eaten with some condiments form one of the commonest dishes with us. The roots are sometimes pickled in miso. There are many other ways of preparing this valuable vegetable for table use, but a longer description would be interesting or amusing only to the curious. Each country has its own *Victua* to inspire it with oracles in the mysteries of national taste and national cookery. American housewives will naturally turn to a Mrs. Lincoln or a Mrs. Rorer for inspiration on this score, and I may forbear further gastronomic dissertation concerning our plant.

Sapporo, Japan.

Inazo Nitobe.

## Plant Notes.

### *Lilium pardalinum*.

THIS is another of the Turk's Cap Lilies, and is nearly related to *Lilium superbum* of the Atlantic coast of North America. *Lilium pardalinum* is found throughout the Coast Range, the Sierras and the Cascades, from Mono County, in eastern California, and San Luis Obispo County on the coast side, to the British Columbian coast, and north-east to Lake Winnipeg. I lack information as to whether it extends farther in southern California, or exists in the high ranges of Nevada and Arizona. As it extends east of the Rocky Mountains to Lake Winnipeg it must exist in at least the northern Rocky Mountains. I should appreciate any information with regard to its distribution in these regions.

*Lilium pardalinum* is usually called a bog Lily, though not altogether correctly. As a matter of fact, while it is found frequently in bogs or wet places, it more often makes its home in open moist meadows, in a sandy soil rich in alluvium, or in deep alluvial deposits along the banks of mountain streams. The bulb, as it is convenient to call it, although it is properly a rhizome, is a curious and interesting study. It may be described as a thick fleshy root-stock, covered closely with one, two or three jointed, closely overlapping scales, which break off easily. Generally, the young rhizome terminates in two or three buds, each of which produces a stalk the succeeding year. As each of these growing buds will in like manner produce from one to three growing bulbs (for lack of a better name) the following year, it is evident that in a term of years very large clumps will be formed. Again, as each growing bulb is produced at an angle to the axis of the growth of the preceding year, branches of the intricate, ramifying rhizome are soon turned around and cross the earlier growth. In this way incredibly large clumps are formed. The rhizome branches two or three deep; the interior ones are compressed and starved, the exterior growing bulbs strong and vigorous, and the entire mass easily traceable to the original parent. The older rhizome becomes yellow, the new growing bulbs are white, and by the scars left on the rhizomes by the succeeding stalks many years' growth can be traced. I have frequently seen masses of from fifty to two hundred growing bulbs, while I once found over five hundred in a single clump on a hillock in a bog. The vitality of the rhizome is great, and pieces cut from the old rhizome will form bulbs. Where a rich, loose soil permits the fullest development, a clump of *L. pardalinum* bulbs is really beautiful. The size, shape and the jointing of the scales vary greatly in different kinds, and although not strictly reliable in their characteristics are an aid in determining the species. Some forms of *L. pardalinum* usually produce but one terminal growing bulb, and in such forms no clumps are produced and the rhizome is long and zigzag.

This Lily grows readily from seeds or scales, and is but little subject to disease. In earlier days it grew in wonderful profusion in some of our mountain meadows, and there are still numerous out-of-the-way places where it treats the hunter or mountain climber to gorgeous displays of color.

Mr. Luther Burbank, the well-known hybridizer, many years ago secured some bulbs of *Lilium pardalinum* near

the geysers in Sonoma County, California. From seedlings of these, selections were made, which on arriving at maturity were cross-fertilized, and this process was repeated several times. I saw a field of the last crosses, and parallels could be seen of nearly every native form of *L. pardalinum*, with giant and dwarf, one-flowered and many-flowered forms which nature had never attempted. Mr. Burbank firmly believes that not only all of our varieties of *L. pardalinum*, but all other Pacific coast Lilies, have a common parentage and have diversified in obedience to environment, and in support of his belief adduces the ease with which all can be hybridized. In this connection I take the liberty of quoting Mr. G. Reuthe, the able superintendent of the Thomas S. Ware Nurseries, in London, on the same subject: "*Lilium pardalinum* seems, in my mind, the easiest for crossing, and I have not the slightest doubt, judging by these results obtained under the most unfavorable circumstances, that most of the so-called species are natural varieties." If Nature, unaided, has not been quite

localities have the same type. As this is true of *L. pardalinum*, it is plain to be seen that, although a description based on a large number of specimens, all drawn from the same locality, may seem to its author quite definite, it becomes of little value when, by a wide acquaintance with localities, we find an endless chain of types varying to one side or the other of the published description. In such a species we may, like Mr. Burbank with his seedlings, select some form of unusual merit which we can maintain by propagation or by continuously collecting from the same locality. From the florist's point this is the proper thing to do. I fear that we will never be able to divide *L. pardalinum* into botanical varieties which the field botanist can follow.

Mr. Baker in his synopsis mentions variety *Californicum*, variety *puberulum* and variety *Bourgaisi*. In *Botany of California* the type and variety *angustifolium* are mentioned, and variety *minor* has also been described, I think, by Baker. The Lily which has been sold incorrectly for

Fig. 17.—Red Cedars in New England.—See page 142.

so lavish of her forms of this beautiful Lily as when assisted by so expert a cultivator as Mr. Burbank, she has yet been overbountiful in varieties of *L. pardalinum*, and I long ago gave up trying to fit them to published descriptions. In identifying or, more correctly, in attempting to identify the many forms which I have met in seventeen years of mountaineering, I had the advantage of Dr. Wallace's *Notes on Lilies*, which is undoubtedly the best guide, and includes Mr. J. G. Baker's *Synopsis of Lilies*. In addition to this, Dr. Wallace some years ago favored me with colored drawings of the varieties of this Lily, according to his work. I have seen plants which approximated these descriptions and drawings, but I have to confess that I have seldom seen or grown lots of this Lily which I could unhesitatingly refer to either variety. It is a peculiarity of many variable species of *Liliaceæ* on our coast, that while in a given locality a vast number of specimens vary within well-defined limits, scarcely two

some years as *Lilium Roezlii* is a form of *L. pardalinum*. *L. Roezlii* proper is different. Some of Luther Burbank's seedlings have been named, and the Thomas S. Ware Nurseries, in London, originated and named several hybrids of *L. pardalinum*. Of these *L. pardalinum*, var. *luteum*, is *L. pardalinum* × *L. Parryi*. *L. pardalinum*, var. *carminatum*, is *L. pardalinum* × *L. maritimum*. Mr. Burbank's beautiful hybrids of *L. pardalinum* on many species have not, I believe, yet been disseminated. In every way the species is extremely variable. I have seen it growing where stalks from seven to nine feet high were common. Four bulbs transplanted from this lot to my garden (a heavy clay loam) produced stalks the first year nine feet high, with from twenty-three to twenty-five flowers on each. Low-growing forms are not uncommon, but under favorable conditions five to seven feet is the ordinary height.

To give any accurate idea of the forms colored plates should accompany descriptions. In default of these I pass

to the forms in which *Lilium pardalinum* borders on other species. *L. pardalinum*, var. *minor*, is the connecting link with *L. parvum*, and being more nearly related to *L. parvum* I will treat it with that species.

In *Lilium Wareii*, as figured and described, we have a species which bears every indication of being the connecting link between *L. pardalinum* and *L. Parryi*. It is a clear yellow Lily, revolute as in *L. pardalinum*, fragrant as in *L. Parryi*. It has a rhizome which clumps up as in *L. pardalinum*, and comes from a region where *L. Parryi* is the common bog Lily. I think it not unlikely that it is a natural hybrid.

*Lilium pardalinum* and *L. maritimum* can be hybridized readily artificially, but, although in some spots the two grow together, I have never seen anything suggestive of natural hybridization.

*Lilium Humboldtii* and *L. pardalinum* grow in the same belt of the Sierra Nevada for hundreds of miles, and although *L. Humboldtii* is a Lily of the hillsides, and *L. pardalinum* of the meadows and stream-banks, they are frequently found close together. I have found but one Lily which even suggested a hybrid. That was in the Bear Valley, mentioned by Dr. Bolander, where a meadow of hundreds of acres was once full of a form of *L. pardalinum*. This is a grand form of the Lily, very heavy and strong, with flowers in which the scarlet scarcely shows at all. My first thought on seeing them was one of wonder that *L. Humboldtii* should grow in such a place.

*Lilium Roezlii* was first described by Regel. Mr. Baker gives as its locality "Rocky Mountains in Utah, introduced by Roezl into European gardens," also in Santa Cruz Mountains, California. It gradually disappeared from sight in Europe, and its very name became a synonym or was appropriated for a form of *L. pardalinum*. Two years ago a collector in southern Oregon wrote me asking if I wished *L. Parryi*, and the fresh flowers he sent proved to be a Lily plainly identical with the original *L. Roezlii*. It flowered freely with me last year, and I find it quite distinct. The bulb is close to *L. pardalinum*, but with little tendency to form clumps. The stem and leaves are pale, much as in some varieties of *L. pardalinum*. The flowers are colored exactly as in *L. Humboldtii*, but are more revolute, and the capsule is like that of the latter or *L. Columbianum*, and very unlike *L. pardalinum*. It grows beyond the range of *L. Humboldtii*, but both *L. pardalinum* and *L. Columbianum* grow in the same region, and it is a good medium between the two.

*Lilium pardalinum* is easily cultivated. The idea that it is a bog Lily has, perhaps, kept many from trying it. As a matter of fact, it is as easily grown in any good garden loam as potatoes. It does not like a soil that is sour and heavy, nor a very light sandy soil, but any fair loam, either sandy or clayey, suits it, and it will stand some manure. As to moisture it is not particular. I have often seen it in ground which becomes quite dry in midsummer. The ideal situation for it is in deep, loamy, well-drained soil close to running water, where its roots can extend down to moisture. It is a Lily to which every flower-lover should give a trial, and in eight cases out of ten it will be a success.

### Southern Californian Ferns.

THE Ferns of southern California are especially noted for their beauty and grace. The California Gold Fern, *Gymnogramme triangularis*, is probably the most widely and favorably known species in cultivation, while the Silverback, or Bronze Fern, as it is sometimes called when old, is a close second in point of popularity. These are both easily grown, at least more easily than some other of our species, which is the main reason for their greater favor with amateurs.

*Adiantum emarginatum* is a special favorite of mine. It lacks, perhaps, the grace of *A. Capillus-Veneris*, or the Maiden-hair Fern of the eastern states (which also occurs in California) but possesses richer coloring and beauty of habit

peculiar to itself. It grows in dry situations with the Gold and Silver Ferns, while the Maiden-hair Fern with us is restricted to perennially moist banks or cañons.

The *Cheilanthes* and *Notholænas* are a distinctive group of Ferns, adapted to a dry climate and able to stand long periods of drought. California and Mexico are both rich in species belonging to these genera—species that captivate the eye of the tourist, but, alas, are seldom responsive to the culture given them by the amateur. Yet they may be induced to grow and flourish by a skillful hand even years after they have been dried and placed in the herbarium.

The Lace Fern, *Cheilanthes Californica*, is one of the best known of southern California species, and perhaps the easiest of successful cultivation. The Cotton Fern, *Notholæna Newberryi*, is scarcely less favorably known to the tourist, and is most frequent in the composite productions with which he returns laden to the east. Cards with elaborately produced pictures, made from dissected Mosses and Ferns, are as familiar souvenirs of the west as the feather pictures brought away by the Mexican tourist.

*Cheilanthes Clevelandi*, a Lip Fern of more local distribution, is rarely seen in cultivation, and seldom enters into California Fern work, except from San Diego. Outside of San Diego its place is occupied by Fendler's Lip Fern, *Cheilanthes myriophylla*. It grows at a higher elevation in the mountains, but is scarcely more susceptible to cultivation.

On the confines of the inhospitable Colorado Desert, in cañons dry throughout a large part of the year, where the scant vegetation is subjected to intense heat, often about 140 degrees, Fahrenheit, we find Dr. Parry's Cloak Fern, *Notholæna Parryi*, *Cheilanthes viscidula* and other Ferns, including what I believe is now properly called *Notholæna cretacea* (referred to in most works as *N. candida*). They are all small-growing species, the *Cheilanthes* seldom over six inches high, and the others with fronds only two to four inches long, as a rule.

The Chain Fern of our mountains, *Woodwardia radicans*, forms a striking contrast with its immense fronds, sometimes measuring ten feet in height, deep in the shade of some ravine with a perennial stream of water beneath its almost tropical luxuriance.

*Pteris aquilina* and *Adiantum pedatum* (the latter rare) are two Ferns which are equally at home in the mountains of California and of New England, and with the local variety incusum of *Asplenium Trichomanes*, our Feather Fern, are the principal species of our Fern flora not closely restricted in distribution.

*Aspidium munitum*, *Polypodium Californicum* and several species of *Pelæa* are peculiar to west America, the latter known as Tea, Wire and Cliff Brakes, locally.

*Ophioglossum nudicaule* is a dwarfish Adder's-tongue Fern, first found by Dr. C. C. Parry in southern California in 1850, and then lost sight of until 1884, when he was the first to rediscover it on our mesas in early spring.

*Woodsia Mexicana* is a rare Fern which I have occasionally found in the mountains of Baja California, near our boundary. We have a few other species, of interest to a botanist, but, I believe, entirely unknown in cultivation and not worthy of special mention.

San Diego, Calif.

C. R. Orcutt.

### *Ouvirandra fenestralis*.

IN the Royal Botanic Gardens at Edinburgh this singular aquatic, commonly known as the Lattice, or Lace Plant, has been very successfully grown for the last twenty-five years. It was started by the late James McNab, who had a happy knack of hitting the right treatment for many newly introduced plants. Since its introduction many specimens have measured over four feet in diameter; the plants flower annually, the seeds ripen and float on the surface of the water where they germinate in a few days after ripening. Seedlings are, however, hardly worth bothering with when old plants are available for the purposes of propagation, as they take too long to make fair-sized specimens. The plants at Edinburgh are grown in shallow oak tubs, about five feet in width; they are placed on a row of hot-water pipes in one of the warmer houses where the temperature of the water seldom falls below sixty-five degrees, Fahrenheit, and ranges from that figure to eighty degrees. The surface water is agitated about three times a week by adding a little water with the hand-syringe. Care is taken to keep the plants shaded from the sun, and when any confervoid growth appears on the leaves the light is excluded for a day or two at a time by means of a tarpaulin drawn over the tops of the tubs.

By imitating those conditions we have been enabled to grow the *Ouvirandra* into quite large specimens in the gardens here;

its greatest enemy is *confervæ*, which will adhere to the leaves whenever there is a sufficient amount of light, but with a heavy shade on the glass of naphtha and white lead this growth can be kept in check. The plants will throw larger leaves when they are shaded from direct sunlight. In places where it is not desirable to have shading, the common *Azolla pinnata* grown on the surface makes an excellent substitute, but this has to be brushed aside in order to see the *Ouvirandra*. The soil for fairly large plants should consist of loam finely sifted three parts, and one part made up of broken charcoal, fine gravel and rotten cow-manure. At potting time this should be mixed and put in a condition which would be considered too wet for potting ordinary plants, so as to prevent the mass from softening in the pot after it is placed in the water. The surface of the pot should be finished off with light-colored gravel or broken rock in order that the fine network of the leaves may be more easily seen. The pot should be just low enough in the water to insure the covering of the leaves, and no more. Should the leaves become covered with sediment of any sort the plant should be taken out and the leaves syringed, one person holding the leaf-blades flat against the hand while another manipulates the syringe. *Ouvirandra* is most easily propagated by dividing the crowns; one fair-sized offset should make eight or ten breaks within a year. The plant dislikes sudden changes in the temperature of the water, and if subjected to such treatment it is almost certain to lose its older leaves, and those which are growing do not attain their full size.

Botanic Garden, Washington, D. C.

G. W. Oliver.

#### Notes from the Botanic Garden of Smith College.

THE raising of seedlings is one of the most important and one of the most interesting operations of botanic garden work, especially where large numbers of species are included. We have some seven hundred species germinated from seed sown this spring. Two-thirds of these are intended for the beds (which are planted in families) outside, while the remainder are greenhouse species and Cacti. To accommodate this number it is important to raise them in the smallest possible space. To this end we sow almost all our seeds in four-inch pots, one species in a pot. We have found this size to be best adapted for the purpose, a size larger being cumbersome, while in a size smaller the soil dries out too rapidly. The tropical species and Cacti are raised in the propagating-house, which is kept at a temperature of about seventy degrees. The hardy and cool greenhouse species are raised on the north side of the warm temperate house, on a temporary stage, which brings them as near the glass as possible. We have found that hardy perennials germinate much better in a temperature of fifty-five degrees than in a cooler temperature. We use a light rich soil, made very fine and porous on the surface. For the Cacti the pots must be well drained, and we usually mix a little powdered charcoal with the surface soil, and also a little more sand than for ordinary seedlings, as they have to remain in their seedling pots for one year at least, and often three years, according to the genus. *Cereuses* and *Opuntias* may be potted off singly in one year, while the slow-growing *Mamillarias*, *Anhaloniums*, *Echinocactus*, etc., require two years at the least before they are sufficiently rooted to pot singly.

All the seedlings require careful watching in regard to watering especially, and if any show signs of damping they must be transplanted into fresh soil at once, and this is generally a preventive. As we only require about eight plants of each of the hardy perennial seedlings, we transplant them into two other four-inch pots as soon as they are large enough to handle; these by the end of May are of suitable size for planting, either in their permanent position or in nursery lines for fall planting. This method of raising seedlings, I think, might be employed with advantage commercially, for as many as two or three hundred seedlings of some species may be germinated in a single four-inch pot.

Northampton, Mass.

Edward J. Canning.

#### Rose Hybrids.

ROSA WICHURAIANA is a plant probably familiar to most of the readers of GARDEN AND FOREST, since its peculiar characteristics and merits were first noted in its columns. The general garden public has had its attention more especially called to it lately under the name of the "Memorial Rose." It is doubtful whether superintendents of trimly kept cemeteries have welcomed it as a boon, for it is a great Rambler and not a plant to be allowed over grass. On sandy, bare soil where few things will grow, or over sloping banks or rocks, it is very

valuable and effective, being not only a rapid, vigorous grower, but perfectly hardy in the worst seasons. Its thick, smooth leaves are little subject to insect pests. Its principal value for ordinary positions, however, would be for use as a pillar Rose, a class of plants for which purpose we have comparatively few varieties that make very long growths and are entirely hardy. The fragrant, beautiful clusters of the single white flowers leave little to be desired. It seems to hybridize readily, and Mr. W. A. Manda, of South Orange, New Jersey, has secured a lot of charming hybrids which have all the merits of the parent plant in hardiness and vigor, and have in addition a great variety of flowers. Mr. Manda has made crosses with a number of tender Roses, mostly Teas, and has secured flowers which are single, semi-double and very double, and white-pink and dark pink (or rose) in color. Last week in Mr. Manda's propagating-house there were some of the double-flowered plants which had been lifted, cut back and forced into bloom. This variety, known as "Manda's Triumph," has a snow-white flower with petals perfectly imbricated and about two inches in diameter. They grow in clusters of twenty-five to fifty or more blooms. One of the prettiest of these hybrids is a single-flowered pink one, known as the "Roamer." There is also a variety which has only a slight suffusion of pink in the white.

These are not forcing Roses, however, and I was drawn to South Orange mostly to see how the plants had wintered in the open, where they had been exposed on a sandy bank. Plants said to be hybrids with *Madame Hoste* and *Meteor* had old growths in some cases twelve feet long, and these were alive for their full length; in fact, the plants seemed entirely unaffected, except in some soft late growths, and these in some cases were not entirely lifeless. These hybrids seem to me an interesting and valuable genus.

Elizabeth, N. J.

J. N. Gerard.

#### Bamboos in Florida.

THE most striking and interesting features in many Florida gardens are the immense clumps of Bamboos. Planted with the charming evergreen *Magnolia*, the striking *Camphor Tree* and such Palms as the massive *Phoenix Canariensis* or *Cocos Australis*, they always command attention by their distinguished appearance.

While on a visit to Florida last November and December I paid special attention to the different species of these giant Grasses found in cultivation. The tourist gets the first glimpse of them while crossing the southern parts of Alabama and Georgia. On both sides of the railroad track there are to be seen in moist ground almost impenetrable masses of our native *Arundinaria macrosperma*. In the lower Mississippi valley, as far north as southern Illinois and Indiana, immense stretches of the low ground are covered with these "canebrakes." The first specimens of the more ornamental Asiatic species I found in the St. James Park at Jacksonville, Florida. I frequently occupied a bench underneath a few broad spreading *Hollies*, *Ilex apoca*, about twenty feet in height, to enjoy the beauty of a magnificent clump of *Arundinaria Japonica*, *Bambusa metake*, scarcely seven yards away. This plant is about twelve feet high and twenty feet in diameter, forming a semi-globular mass of the densest and richest green imaginable. The stems, which are highest and strongest in the centre, are not crowded in a mass around the root-stock, but they stand from one to two feet apart. Every stem stands upright and is furnished two-thirds of its length with broad evergreen foliage. All the culms clustering around the plant are smaller and shorter than those more in the centre. Mocking birds and many of our feathered winter sojourners, like juncos, white-throated and white-crowned sparrows, catbirds, etc., find exceedingly congenial and safe retreats among this mass of green. This particular specimen is so beautiful that it is worth quite a journey to see it. Having been planted five years ago it was killed to the ground during the great freeze on February 7th, 1895. At present it is as beautiful as ever. There are several smaller specimens in the same ground, which in a few years will have attained the same proportions. Several plants of *Bambusa argentea* (probably *B. verticillata*) do not look as promising, and *B. vulgaris* is not at home so far north.

The most beautiful as well as the largest Bamboos were seen in the gardens of Orlando, over a hundred miles farther south. The species commonly met with is the large unarmed Bamboo of Bengal, *Bambusa vulgaris*, usually called the Giant Bamboo. Everywhere in the charming subtropical gardens in the town it forms masses of noble aspects. When well established, heavily fertilized and frequently watered, it grows at such a rapid rate that in the course of about five or six years immense clumps thirty to fifty feet high, and as much in diam-

eter, are formed. Several specimens are known whose stems have reached their full height of over seventy feet in sixty days. The first growth of canes is usually made by the middle of July. All the buds that start after the middle of September perish, and no more growth is made until the following July. The culms in their first season stand erect with few branches and with only terminal leaves. The second season they feather out and become heavy with foliage, curving over gracefully to all sides. During the disastrous freeze of February 8th, 1895, all the specimens of this Bamboo were killed to the ground, but they pushed up new shoots in July, and at present no trace of the frost is visible. Clumps forty to sixty, and even seventy, feet high, and as much in diameter, are very picturesque. All the stems are crowded together around the root-stock, the exterior ones especially arching over to all directions by the heavy weight of the dense mass of foliage. In one of the larger gardens where grand masses of Bananas, a great clump of *Alpinia nutans*, about ten feet high, immense specimens of Pampas Grass, and a fine tree of the common Date Palm surround it, this Bamboo is at least sixty or seventy feet high, the immense culms gracefully arching over, covering at least a space of a hundred feet in diameter. This clump stands on low ground and near a hydrant, where it is frequently watered during dry weather. The abundant, large, velvety foliage of this species has a slight trace of yellow in its green color, which gives it a distinct individual quality. It never forms suckers at any distance from the root-stock like most of the species of *Phyllostachys*, which become a nuisance when not constantly watched and kept within bounds.

*Bambusa arundinaria*, the Thorny Bamboo of India, is almost as beautiful as *B. vulgaris*, and it grows much in the same manner. As its stems are stronger they stand more erect and do not arch to all sides. At a distance a small specimen looks much like a gigantic Tree Fern. It is not as yet a common species in the gardens, and there are only a few specimens planted a few years ago that have attained a height of scarcely twenty-five feet. There is a pretty specimen on my place on high Pine land that is very promising. The prospects are that in a few years hence this species will rival in beauty and size the *Bambusa vulgaris*.

*Dendrocalamus strictus* is an exquisite species of gigantic proportions. Of late years it has been distributed over many parts of the state with *Bambusa arundinacea* by the wide-awake firm of Reasoner Brothers, of Oneco, Florida. As it flourishes to perfection on high and dry Pine land it is of particular value. The species is difficult to propagate, and therefore it will only become more abundant in the course of time. All the specimens I have seen were young plants, but in a few years they will have grown into gigantic clumps. The strong culms are crowded together around the root-stock, and they are scarcely arching over on the sides. Like the two foregoing, this species is strictly tropical, young unprotected plants having been killed outright when the mercury fell as low as nineteen degrees, Fahrenheit, on February 7th and 8th, 1895. It is said to be one of the mightiest Bamboos in existence, reaching a height of over one hundred feet in its native country, India. It has not been grown long enough in Florida to say with any certainty what size it will acquire.

The most common Bamboo in the gardens of Florida is *Bambusa argentea* and its variety, *B. argentea striata* (probably this is *B. verticillata*). I have found many magnificent specimens even in the gardens of the backwoods. The leaves of the type are of a rich green, with a glaucous underside, while in the variety they are prettily variegated with creamy white. Specimens twenty feet high are frequently met with, and the root-stock of such is estimated to weigh several tons. All the canes are crowded together, arching over on the sides near the ground. In the centre they all stand upright. The tops of the stems are not furnished with masses of foliage like the foregoing species; in fact, in the upper half the foliage is rather scant, the density of the plant being lower down. It is a plant of great beauty, though much less ornamental and refined than the foregoing species. It grows well on high dry Pine land, but there its leaves are of a rather yellowish hue.

*Thamnocalamus Falconeri* (*Bambusa falcata*), from the Himalaya region, I have only seen on my own place in Orange County. It is a small but exceedingly beautiful plant, rarely growing more than ten or twelve feet high and as much through. Its thin slender stems are densely clothed with small Fern-like foliage of a beautiful light velvety green color; the underside of the foliage has a glaucous hue. In my garden I have also the following species:

*Phyllostachys violascens*, *P. Nigra*, *P. aurea*, *P. viridi-glaucescens*, *P. Castillanis* and *Arundinaria Simoni*, all desirable species. Though planted several years ago, they have not

made large clumps as yet, but some of them have sent suckers to all directions, so that my man has difficulty to keep them in bounds. Like most Japanese plants, they appear to be perfectly at home in Florida, and they would have formed strong specimens were they planted in moist rich soil. *Phyllostachys Nigra* has jet-black stems, and *Arundinaria Simoni*, which grows thirty feet high, is distinguished by its many fine branches and dense masses of small variegated leaves. A part of my grounds near the beautiful small Lake Audubon, where the soil is deep and moist, has been set aside for a Bamboo garden. Those planted out already flourish admirably.

There are quite a number of other beautiful tropical Bamboos which should be introduced by our enterprising nurserymen. To do their best, Bamboos need much water and a very deep rich soil. They need heavy fertilizing, and should be mulched each year with a thick layer of stable manure.

Milwaukee, Wis.

H. Nehrling.

## Correspondence.

### Notes from West Virginia.

To the Editor of GARDEN AND FOREST:

Sir,—By a very natural error in punctuation I was made to say in No. 476 of GARDEN AND FOREST that such plants as *Saponaria ocyroides*, hardy Candytufts and Creeping Phloxes were a mass of bloom in my garden late in March. What I meant to say was that these plants were masses of healthy evergreen verdure. Even in the earliest of springs I have not seen any of these plants in bloom before the middle of April, and up to this time (April 8th) none of them have shown a flower. We have now, however, enough early bloom to make the garden bright and to repay richly all our care. The most conspicuous ornaments of the home grounds at present are some fruit-trees, planted for their beauty and also to screen outbuildings, in which latter position they have evergreens for a most effective foil and background. The first of these to flower were the Hard-shell Almond-trees, which are not often planted for ornament, but which are very charming when used in this manner, as they have large pale pink blossoms very early in the season. These were quickly followed by the Nectarines and Apricots. The bloom of all these trees comes before the leaves, and therefore the background of evergreen foliage is necessary to bring out their full beauty. A large old Plum-tree planted close to the south side of the house was two days later than the Almonds in flowering. I do not know the name of this Plum, which is at least twenty-five years old. It bears no fruit, but at blossoming time it covers itself with delicate bloom and tender green foliage, and it is earlier by about a week than *Prunus Simonii* and the Purple-leaved Plum, now just coming into flower. There is no tree like it in this neighborhood. I have no *Prunus Davidiana* with which to compare it in earliness of bloom.

The dull chocolate-colored flower-sprays of the little shrub, Yellow-root, *Zanthorhiza apiifolia*, are interesting, but neither fragrant nor showy, and the plant does not seem to thrive in our soil, as it does not spread or increase in size. It is associated with Spice-bushes and Leatherwood in the shrubbery, all of which bloom at the same time and suggest our native cypresses. It is therefore well to plant them together in the wilder parts of the home ground where these are of ample size. Forsythias are now in full bloom, and are, of course, the most conspicuous of early-flowering shrubs.

The Japanese Weeping Cherry is expanding its flower-buds of rich carmine, which develop into blossoms of a paler shade. The ground around our largest Weeping Cherry, which is a beautiful full-grown tree twenty feet in height and of most graceful and picturesque habit of growth, is carpeted with single Hyacinths, white, pink, buff and blue, naturalized in the grass. It is true that Hyacinths deteriorate in size of bloom when planted in this manner, nevertheless the effect of this grouping about the Weeping Cherry, with its long pendent branches clothed in delicate rose-color, is very good, and much more to our taste than the stiff rows of double-flowering Dutch Hyacinths one so often sees primly disposed on naked soil in a garden-bed.

We are now much interested in establishing a wild garden for hardy Ferns and wild flowers from the cliffs of the Potomac, which rolls past our little village, and from the neighboring country. Expeditions to these cliffs result in adding to our collection as many as eight species and varieties of Fern in a single morning. We plant them in crevices of the rocks and on and around stumps of trees, set in their native Mosses, for almost all of these Ferns grow naturally on Moss beds that cover the overhanging rocks of the river cliffs. Hepaticas

and Columbine, Rock Cress and Saxifrage and many other wild flowers are planted with the Ferns. We feel sure, among other delightful "finds," that we have discovered *Sedum Neviusii*, a rare plant, growing on our cliffs. This *Sedum* was discovered and named a generation ago by Dr. Nevius, a clergyman of Alabama, on rocky cliffs near Tuscaloosa, in that state. It has also been found—I quote from Mr. Meehan, in his *Native Flowers and Ferns of the United States*—on Salt Pond Mountain in Virginia. We are impatient for its bloom, in order that we may be sure we are not mistaken in supposing that our plant is the true species.

Delicate pink and white Rue *Anemones* are now blooming in our fernery in company with graceful fronds of common *Polypody*, beds of Walking Fern, tiny plants of *Asplenium Trichomanes*, *A. Ruta-muraria* and larger plants of the Rock Brake, *Pteris atropurpurea* and its near relative, *Pteris gracilis*. Here, also, we have our collection of Mosses of this region, but, alas, I am not enough of a botanist to know even the names of most of them. What book on American Mosses and other flowerless plants would be the most helpful to an amateur botanist who wishes to begin the study of these plants?

Rose Brake, W. Va.

Danske Dandridge.

[On Mosses, Lesquereux's *Manual* is the standard work, and Barnes' *Key*, published by the University of Wisconsin, should go with it. On Ferns and Hepaticæ the chapters in the last edition of Gray's *Manual* or Underwood's *Native Ferns* can be consulted.—Ed.]

### The Nomenclature of the Spruces and Firs.

To the Editor of GARDEN AND FOREST:

Sir,—I trust you will give me a little space in the columns of your journal for a few remarks upon the nomenclature of the Spruces and Firs, in which I am much interested, and especially so since the discussion of this subject by Mr. Jack and Professor Greene has appeared in this journal. I, in common probably with many others, have noticed the difference between the dates of publication of the genus *Abies* and of the species *A. balsamea* as given in several of our recent publications. The publication of the species is made to antedate that of the genus by twenty-one years, an oversight which is scarcely excusable in those who have made the subject of priority of publication a matter of special investigation. Professor Greene says that Duhamel published a genus *Abies* in 1755, but fails to state what his type was; was it limited to *Abies* as at present understood, to *Picea*, to *Tsuga*, or did it contain all of these genera? I trust that Professor Greene will enlighten us upon this point, as it is a most important one, for, if it does not apply to *Abies* as at present understood, it will necessitate a shifting of generic names and new combinations. Now, in reference to *Abies Canadensis*, Miller, *Dict.*, ed. 8, No. 4 (1768), I think it can be shown that it is nothing more than a synonym, pure and simple, of *Pinus Canadensis*, L., *Sp. Pl.*, ed. 2, 1421 (1753). In the latter work Linnæus uses the descriptive phrase, "*P. foliis solitariis linearibus obtusiusculis submembranaceis*," quoting as primary synonymy, "*Abies foliis solitariis confertis obtusis membranaceis*, *Gron. Virg.*, i., 191," and as a second synonym, "*Abies foliis piceæ brevioribus, conis parvis biuncialibus laxis*, *Mill. Icones*, i., t. 1" (1760). Five years later Miller published his *A. Canadensis*, first using Linnæus' descriptive phrase, "*P. foliis . . . submembranaceis*," and adding as a second synonym his own earlier description, "*Abies foliis . . . laxis*," just the same as Linnæus had done under *Pinus Canadensis*. Therefore, as the description and principal synonym of *Abies Canadensis*, Miller, is the same as for *Pinus Canadensis*, L., and, in fact, is mainly taken therefrom, the two names must be considered as applying to the same plant, which is the Hemlock, *Tsuga Canadensis* (L.), Carr. As indicated by Professor Sargent, the proper name for the White Spruce should be *Picea laxa* (Ehrh.), Sarg.

Detroit, Mich.

O. A. Farwell.

### Notes from Carlton Hill, New Jersey.

To the Editor of GARDEN AND FOREST:

Sir,—The sixty or more hot-houses of Mr. Julius Roehrs are near Carlton Hill, New Jersey, twelve miles out on the Erie Railroad. Much of the stock seen here last week was for the Easter trade, and many of the houses were brilliant with bloom. However, in so great an establishment much space was occupied by plants grown for other seasons. Not a few of

the houses, for economy in wall-space and heating, are unseparated, except by supports of cedar posts, and eight adjoining houses, each one hundred or more feet in length, made a luxuriant field of Palms and other foliage plants. These have almost no demand now, and are the specialty for autumn trade, as plants in flower are for spring. A house of *Araucarias* was particularly beautiful and very thrifty, as, indeed, were all the foliage plants. The type, *Araucaria excelsa*, and the varieties known as *Glaucia* and *Robusta* are all grown in quantity; the deep green of the older leaves and the tips of new growth of a lighter shade made a beautiful effect in the great collection of plants now three years old and imported from Belgium two years ago.

Among the less common flowering plants for Easter were a house of French Lilacs, those intended for market now about two feet high and well covered with opening trusses. Specimens of the once popular Bottle-brush, *Metrosideros*, were well flowered, as were trimmed plants of *Bougainvillea Sanderiana*, which Mr. Roehrs considers extremely useful on account of its dwarf habit and its abundant flowers, which can be forced at this season. About a dozen plants of the Rose *Acacia*, *Robinia hispida*, were observed with their deep pink flowers. The selected plants of *Kalmia* ready for Easter looked well to the casual observer, though Mr. Roehrs said the imported stock proved poor and unsatisfactory this season. The distinct tints of thickly flowered plants of Ghent Azaleas were conspicuous, and very densely berried plants of *Ardisia crenulata* made a brilliant display near the green and white of a collection of *Choisya ternata*. The latter has a very uncertain sale, as it is but little known. There were plants of *Cytisus* and of *Acacia racemosa* three feet high, the spiny branches closely covered with the small leaves and globular clear yellow flowers. Moss Roses, Baroness Rothschild and Ulrich Brunner Roses filled several houses and bore a plentiful supply of buds. Mr. Roehrs considers these two hybrid Roses the only ones which bloom freely enough to compete with the steadily improving Tea Roses. He remembers when Magna Charta roses were readily sold for \$18.00 a dozen at wholesale for Christmas, while \$6.00 is their current value in midwinter. Too many of the hybrid Roses come blind, and thus prove unprofitable, while Tea Roses bloom naturally and continuously. There is, however, no great profit in growing Baryness Rothschild and Ulrich Brunner specially for Easter, as the time cannot be accurately measured, and some of the roses are mature two weeks earlier than Easter, and must be cut, while slower plants are belated a fortnight in flowering.

Lilies, Azaleas, Rhododendrons and Hydrangeas comprised the main Easter stock. Only *Lilium longiflorum* was grown here this year, some 7,000 bulbs being in flower, and these tall stalks bore an average of five exceptionally large and vigorous buds. Most of the Azaleas were of medium size for use in ordinary living-rooms, though there were some large plants which will be returned by their temporary owners after the flowering season is past. Three to four thousand of these showy plants comprised all the best varieties and colors. So much time and money is necessary to grow large plants to perfection that Mr. Roehrs finds those of medium size more profitable, and they are also in greater demand. But even these have dropped one-third in price in recent years. The most showy Azaleas were plants of the brilliant carmine Le Flambeau; Siegfried, a clear scarlet with a suggestion of salmon, and almost free of marking; C. B. Brigham and Apollo, of a deeper shade; Helen Thildeman, a good double pink; Professor Walter, darker than *Vervæneana* and an improvement on this popular pink variety. Bernhard André alba was the best white seen here, and Raphael is a little sensitive so late in the season; these, with Garten-director of France, white, with markings of scarlet in clearly defined sections, were among the best sorts. About three hundred plants of Rhododendrons of various species were in flower. The houses of Hydrangeas were hardly less showy than those of Azaleas, and compact plants carried good heads of many-colored flowers, various shades of blue, pink, lavender and green making a unique effect.

Narcissi are sparingly grown, and most of the Tulips were white ones, the green-tipped flowers making a pleasing show in the leathery glaucous leaves. Lily-of-the-valley is one of the staple crops here, and about 100,000 pips were being forced.

Orchids are grown for cut flowers, and four houses contained resting plants of *Cattleya triana*, *C. Mossiæ*, *C. Gaskelliana*, *C. labiata* and *Dendrobium formosum*. A house of *Swainsonia* was observed, and a group of standard Orange-trees two feet high and coming into fruit, besides smaller Otaheite Oranges in flower. Forced hardy shrubs were once a specialty with

Mr. Roehrs, such as flowering Almonds, Deutzias and Spiræas, but their blooming season is short, so that it is difficult to have them at their best at exactly the right time, and then they do not keep longer than a few days in the buyer's hands. The lateness of Easter this year has had a favorable effect on the plants, which have been forced gradually, with no hurry, and it is always easier to hold plants back from flowering than to urge them in advance.

New York.

M. B. C.

### Notes.

New-crop limes from Jamaica, small and green, may now be had at fifteen cents a dozen, or \$1.25 for 100.

A consignment of 180,000 Easter lilies arrived in this city on Sunday by the regular steamer from Bermuda.

Trailing Arbutus, from woodlands in Massachusetts and other neighboring states, is the newest offering in the up-town flower-stores, and a compact little bunch costs but twenty-five cents.

It must not be considered that the few western Senators who make most of the noise in Washington against President Cleveland's forest reserves represent the best public opinion of their section. The Senators and Representatives of California all support the reservations, and on the 27th of March the Sierra Club of San Francisco passed a series of resolutions which endorse the action of the state's delegation in Congress, favor the reservation principle and urge that as far as possible the forests thus set apart shall be policed by the army.

Professor Roberts, of Cornell University, is sending out circulars to notify whom it may concern that under the Agricultural Extension Bill the college of agriculture of that university has undertaken to assist, free of expense, all teachers who wish to introduce what is called "nature studies" into the public schools. Nature study means nothing more than seeing familiar things in a new light, and the Cornell faculty wish to encourage the investigation of common objects so as to teach accurate observation and the power of clearly expressing what is seen.

Mr. F. W. Burbidge, in an address on the culture of hardy bulbs in England, said that 100,000 Hyacinths or Narcissus may be grown on an acre of land, 115,000 to 120,000 Tulips, while of smaller plants like Crocuses, Snowdrops, Squills, Anemones, Winter Aconites, etc., the number runs up to 200,000 and 300,000 an acre. He believes that any hardy bulb which brings more than one pound a thousand in the market can be cultivated with profit in many parts of England. Professor W. F. Massey, of North Carolina, has long been of the opinion that the cultivation of bulbs could be made a successful industry in that state.

Mr. Wilhelm Miller, who is a special student of horticulture in Cornell University, has prepared a bulletin on Dahlias, which is published by the experiment station, and which is much more than a mere test of varieties although it gives the habits, form and relative value of some 350 different named varieties which were grown at Ithaca last year. In the first place, there is an interesting history of the plant and of its evolution to its present freedom and grace of outline and poise since the introduction of the Cactus Dahlia. The illustrations show some of the best forms of the flower which recent crosses have produced, and the thirty-five pages which make up the bulletin are all filled with interesting and instructive matter.

Professor Morse, of the New Hampshire Experiment Station, writes to the press of his state that ashes are now delivered in car-load lots at railroad stations at \$10 a ton. This low price, however, is accompanied by a deliberate reduction in the quality of the ashes. Buyers should look with suspicion on lots which appear excessively moist, for in such cases the potash is seldom equal to the proportion in the average product. Certain samples analyzed were from burned rubbish, principally of waste paper and refuse lumber. It is a fact which should be generally known, that ashes from paper are as valueless as ashes from coal, because the soluble mineral matter has all been leached out of the paper stock during the process of manufacture.

We have already spoken of Professor Halsted's experiments with Potatoes with reference to the disease known as the scab, Oospora scabies, and a recent bulletin gives interesting details of the work of the last year. It seems to be proved that the

soaking of the seed potato in a solution of corrosive sublimate will not greatly check the disease if the soil itself is infected, although if the poison is added to the soil it will check the scab. Sulphur maintained its position as the best remedy, and its wholesome effect on the soil remains undiminished through the second year, and no one knows how much longer it will prove useful. Kainit, besides being a good fertilizer, has been proved to have a considerable fungicidal value.

The Saghalien Knotweed is a strong perennial herb with creeping root-stocks, and it has been cultivated for twenty-five years in the botanical gardens of Europe. A few years ago, in time of drought in France, it was discovered that cattle would eat the leaves and tender branches of this plant, and the suggestion was made that it might prove valuable as a fodder-plant. In a year or so extravagant accounts of the value of this Polygonum Sachalinense appeared in some American seed catalogues, but the Director of the Maine Experiment Station issues a renewed warning against trusting it. It is not probable that American farmers will realize the hopes which have been raised by the glowing descriptions of this plant from Europe. We should be very glad to publish the experience of any one who has tried it.

The sweet or saccharine Sorghums are now successfully grown in almost every state and territory of the Union, and although there has been a decrease in the acreage of these Sorghums planted for the manufacture of sugar and molasses, the acreage sown for forage has increased very materially. Mr. Thomas A. Williams, the Assistant Agrostologist of the Department of Agriculture, has prepared a bulletin on Sorghum as a Forage Crop, which in the scope of twenty pages groups together the results of experiments in many of the stations and elsewhere throughout the Union. Among the facts brought out are that Sorghum endures drought better than Corn, and will do better on thin soils, being a stronger feeder; that the early varieties are preferable for forage; that the seed should not be sown until the ground becomes warm, and then plenty of it should be used in a well-prepared bed; and that irrigation should be practiced where it is possible. It is good practice to plant Cow Peas or other Legumes with the Sorghum, not only to improve the quality of the forage, but to leave the land in better condition. The crop can be used for soiling, pasture, ensilage or hay, and the best quality of hay is obtained by cutting the plant shortly after it begins to bloom. For soiling it can be cut profitably as soon as the heads are formed, while for silage it is best cut when the seed is in the "dough." Sorghum is a native of the tropics, but it is a most adaptable plant, and varieties have been developed which are perfectly hardy as far north as Canada, and every one who has a farm and reads this bulletin will be tempted to experiment with it as a forage plant.

Above 51,000 packages of fresh vegetables from the south were received in New York during last week. Besides 20,000 barrels, crates and boxes of new cabbage, peas, beans and tomatoes, there were thirty-four packages of cucumbers, 728 of lettuce, 17,318 of spinach, 12,195 of kale, 4,051 of radishes and 1,394 of asparagus. This does not include receipts of vegetables forwarded by express, but the general shipments by steamships and ordinary passenger and freight trains. Besides these domestic products, there were onions from Bermuda, Spain and Turkey, and potatoes from Scotland, Germany, Bermuda and Cuba. Asparagus now comes from North and South Carolina and Virginia, and the first cuttings are being shipped from Maryland. The white shoots cost forty-five cents, and the tender green stalks fifty-five cents a bunch in Washington Market. Beets, from Florida and South Carolina, bring ten cents a bunch, and cabbage, from the same state, ten cents a head. Celery comes from California and Florida, and cucumbers from the latter state and from Boston hot-houses. Eggplants from Florida command twenty to twenty-five cents. Kale comes from Maryland and Virginia, as does spinach. Peppers are supplied by Florida, as are string-beans, lettuce, squashes and tomatoes; the latter now sell for twenty-five cents a pound. Peas, from Georgia and South Carolina, sell for seventy cents a half-peck. Radishes come from Virginia, and parsley from Bermuda; 26,500 crates of onions came from these islands last week, also 800 barrels of potatoes, which bring fifty cents a half-peck at retail. Sweet potatoes, from southern New Jersey, cost twenty-five cents a half-peck. Dandelion gathered from fields and commons brings ten cents a quart, and that which is cultivated and blanched realizes twice that price. Okra costs ten cents a dozen, and mushrooms fifty cents a pound.

## The Care of Park Trees.

WANT of technical knowledge makes it easy, apparently, to discuss in print the complex and often difficult conditions which affect trees in urban parks, and makes their critics peculiarly eager to blame park managers when they attempt to improve park plantations by necessary thinnings. Ill-advised protests against cutting trees menace the beauty and usefulness of every American park, and in some of our cities this has been carried to such a point that park commissioners and superintendents are so intimidated that the plantations under their charge are abandoned to their fate, or, if a tree has to be cut down, it is done surreptitiously. We have over and over again called attention in these columns to the importance of judiciously thinning park plantations, taking the side of experts against theorists, and maintaining that if the greatest possible enjoyment is to be obtained from public parks they must be managed by men who understand their business.

This subject has recently been attracting a good deal of attention in Boston, where correspondents of the daily papers, usually signing themselves "artist," have been vigorously protesting against the much-needed thinnings which have been made this year in the park plantations. Boston a few months ago was fortunate in securing the services of an educated, well-trained and efficient Park Superintendent, who has become the executive of the Board of Park Commissioners. The new Superintendent saw at once that the park plantations placed in his charge were in a deplorable condition. The trees, as we pointed out in these columns a few months ago, were overcrowded, full of dead wood, improperly nourished and suffering from the attacks of various insects. Nothing had ever been done to these woods and groves since the city purchased them several years ago, and they have been in an unsatisfactory and dangerous condition. The first thing to be done, of course, under such circumstances is to remove dead and dying trees, to cut out unnecessary saplings, which often spring up like weeds in neglected parks and plantations, and to furnish room and admit light to the more promising trees. This the new Superintendent

proceeded gradually to do, and it is this attempt to improve the Boston parks which has raised such a storm of protest from persons who, forgetting that parks are not primeval forest, declare that the natural beauty of the Boston park woods and plantations is being destroyed. Such critics never remember that provision must be made in parks for the free enjoyment and circulation of great crowds of people, and that in order to afford such facilities for the public natural forest conditions must be more or less sacrificed. Few people realize that the sylvan charms they plead for can only be secured with the aid of healthy trees, and that trees which are overcrowded, half-dead and full of insects can never produce the results they demand. Segregations of human beings in cities and their suburbs so change natural conditions that woods in urban parks cannot be left exclusively to the care of nature, however attractive this may sound in the mouths of enthusiasts; and man must adapt his plantations to the unnatural conditions he has provided for them.

This whole subject is of such vital importance in its relation to the artistic and practical value of American parks that we have taken occasion to examine carefully the effects of the tree-cutting which has been done in the Boston parks during the past winter, and our criticism upon it is that the new Superintendent, desiring probably to feel his way in a community new to him and unfamiliar with local conditions, has nowhere yet sufficiently thinned the plantations in his charge, and that the Boston parks, like those in every other American city with which we are acquainted, are still suffering from insufficient tree-cutting.

## A Garden for Children.

WE have already called attention to a series of leaflets prepared for the teachers of rural schools in the state of New York, under the direction of Professor Roberts, Director of the Ithaca Experiment Station. Under a state law enacted for the purpose of extending the work of the experiment station so as to give an impulse specifically educational to the farmers of the state, several plans are under trial. Itinerant or local experiments have been used as a direct means of teaching. Bulletins have been issued on various subjects like apple-culture, etc., in which the theory and practice is briefly explained, and the history and condition of different branches of rural industry have been written in an attractive way. Horticultural institutes or schools have been held in different towns and cities of the state, and courses of reading have been prescribed in connection with correspondence with the teachers in the Agricultural College. One of the latest efforts is an attempt to establish the study of nature in rural schools, and it is to encourage this that the leaflets of which we have spoken have been prepared. These little bulletins were primarily intended for the teacher, and were meant to suggest the ways in which he can interest his pupils at odd times in some natural object or process. Of course, they may be given directly to the advanced pupils for the purpose of suggesting to them experiments and observations and for encouraging them to examine objects for themselves to form conclusions of their own and to state them in their own language. Four of these illustrated leaflets have been published, in the first of which the pupils are asked to investigate the way in which a Squash-plant gets out of its seed; in the second, a burning candle is the object of study, and in the third they are asked to examine an apple-twig and trace the history of its fruit-spurs, its flower-buds, its leaf-buds, its branchlets, etc. This third leaflet will be found full of interest and suggestion to many grown-up children who call themselves educated. A fourth leaflet is for pupils rather than teachers, and it requests every school child in the state to grow a few plants during next summer. The only way to learn how plants grow is to grow them, and personal investigation is the only way, as the leaflet suggests, in which one can become intelligently interested in anything that lives and grows. The specific request is

that the children shall grow two kinds of flowers, Sweet Peas and China Asters, because the seeds of each are cheap, they are easy to grow, they are handsome and both come in various colors. There are brief instructions about selecting the ground, making the bed, how and when to plant the seed, the varieties to select, and how to care for and water them. In all cases the reasons for a given treatment are suggested. Inasmuch as the experiment station has had a bulletin on each of these plants any one who wants to have more specific knowledge of them is invited to send to the Cornell Experiment Station for these bulletins.

Now, it is not wise to expect too much from any scheme like this. No doubt, there are hundreds of children who will plant the seeds and whose enthusiasm will then die out and they will be left as ignorant as they were before; but any child whose attention has been aroused by his parent or teacher in the manner suggested by the earlier leaflets of this series has his face set in the right direction for the formation of the habit of looking properly at things and drawing correct conclusions from what he sees. If in addition to this the child is asked to write out his observations and conclusions, and to make sketches of his plants at different stages of their growth, he has begun the study of nature in a way that will not only help his intellectual development, but will prove a source of comfort and pleasure to him all his life long. We assume that any child in New York state can have one of these leaflets if he chooses. Perhaps, by a stretch of generosity, the director of the station might send them to places outside of the state. This subject is one of great interest and we shall recur to it again. Meanwhile, we hope that any reader of GARDEN AND FOREST who can do so will persuade some boy or girl to try a little garden of these two plants, for there is an advantage in limiting the study to a few kinds only. A place four feet wide and twenty feet long is as large as most boys or girls will take care of. Half of the ground should be devoted to the Peas, the other half to the China Asters, and four or five distinct kinds in different colors will make enough variety. The leaflets, which can probably be had by addressing the Chief Clerk of the College of Agriculture at Ithaca, New York, give a few necessary directions at the outset, and some suggestions as to the proper line of study will be made later on.

#### Notes on the Pine Forests of Southern and Central Arizona.

MUCH of the forest area of Arizona is in the northern portion of the territory on the Colorado plateau, and our Pine forests reach their highest development in the vicinity of the San Francisco Mountains. From here they stretch northward to and beyond the Grand Cañon of the Colorado River, westward to Bill Williams Mountain, and southward to the rim where the Colorado plateau breaks down to the southern plains. This is what is generally known as the coniferous forest area of Arizona. In addition to this, Arizona has considerable timber in the south and central portions of the territory. The many mountain ranges south of the Colorado plateau, reaching an elevation of 7,000 feet, have more or less extended areas of cone-bearing trees. It is of these forests that I desire to speak.

The Bradshaw Mountains, Mogollon Mountains, Mazatzal Mountains and the White Mountains may be considered as southern extensions of the Colorado plateau. Of these mountains the Bradshaw Mountains are the most poorly supplied with Pine timber. The forest area of this range of mountains is mostly in the vicinity of Prescott, extending from here about twenty or twenty-five miles south and south-westward. The Mogollon Mountains and the Mazatzal Mountains are separated from the Bradshaw Mountains by the Verde Valley. Both of these ranges have wide strips of Pine along their summits. The White Mountains are well timbered with White and Yellow Pine, some of the most valuable Pine in the territory being on these mountains.

Immediately south of these are a number of lower ranges, namely, the Pinal, Superstition, Caliuero and the Gila Mountains. All of these ranges have a narrow fringe of Pine along their summits, varying from a few yards to a half mile in width, and in places extending for some distance down the cañons.

In the south and south-eastern portions of the territory, south of the ranges mentioned, are a number of others with summits reaching to, or nearly to, the height of 10,000 feet. All of these mountains are well timbered above the altitude of 7,000 feet. Enumerating these ranges in their order, beginning in the very south-eastern part of the territory, we have the Chiricahua, the Huachuca, the Santa Rita, the Rincon and the Santa Catalina Mountains. The entire western and south-western portions of the territory have no high mountains and are therefore entirely destitute of cone-bearing trees. Between the high southern ranges are a number of lower ranges, namely, the Whetstone, the Dragoon, the Mule, the Tucson and the Pinaleno Mountains. These ranges are all destitute of Pine, or have very restricted areas of Nut Pines on their higher slopes.

Confining our attention to the area of Pine in Arizona south of the Colorado plateau, and not taking into consideration our three species of Nut Pine, I should place the areas in square miles as follows: The Bradshaw Mountains have about twenty-five square miles that might properly be termed forest. The forest area of these mountains is nowhere very dense and consists of narrow, broken stretches of Yellow Pine, *Pinus ponderosa scopulorum*, along the highest portions of the range. Below the area of Yellow Pine, at an elevation of about 6,000 feet, is a large belt of Nut Pine, *P. monophylla*, while farther down the mountains are thousands of acres covered with a scattered growth of the small Nut Pine, *P. edulis*.

The forest area of the Mazatzal Mountains may be placed at about seventy square miles. A dense strip of Yellow Pine extends southward from Baker's butte into this range of mountains. Growing with the Yellow Pine at the higher elevations are scattered specimens of White Pine, *Pinus flexilis*; Fir, *Abies concolor*; Douglas Spruce, *Pseudotsuga taxifolia*; while at lower elevations are large areas of Junipers and the two Nut Pines (*Pinus edulis* and *P. monophylla*). The Foxtail Pine, *P. Balfouriana*, var. *aristata*, does not seem to reach south of the San Francisco Mountains.

The Mogollon Mountains have some forty square miles of timber. This area is a continuation of the forests of the Colorado plateau and is very similar to the forests of the Mazatzal range.

The White Mountains are known to be well timbered, but I am unable to state the area of Pine forests upon them. Taking into consideration their area above 7,000 feet and the various species of Pine collected there, it is safe to estimate that at least a hundred square miles of these mountains are more or less thickly timbered with Pine. On the higher portions of this range are considerable areas of White Pine, *Pinus flexilis*, mixed with Fir and Spruce. Many of the cañons are lined with an excellent growth of Cypress, *Cupressus Arizona*. This tree is also found in the mountain ranges to the west. At the Natural Bridge it forms large forests almost to the exclusion of other trees.

The low mountains south of these four ranges, namely, the Pinal, the Superstition, the Galluro and the Gila ranges, altogether have not more than thirty-five square miles of what might properly be termed forest area. This area is almost entirely of Yellow Pine, and is represented by narrow fringes along the summits of the mountains and at the upper courses of the cañons. Much of these mountains, however, is covered with a scattered growth of Nut Pines, *Pinus edulis* and *P. cembroides*. In these low mountains the two species of Nut Pine above mentioned come together, one being a northern species and the other a southern. Below the Pines all these mountains of central Arizona are thickly covered with a dense growth of Scrub Oak, *Quercus undulata*.

The distribution of the Pine forests on the high mountains

of south and south-eastern Arizona is very interesting on account of the number of species represented and the varying preponderance of species on the different ranges. The forest area of the Chiricahua Mountains is about 150 square miles. This area extends almost continuously from the Mexican line to Apache Pass, a distance of about forty miles. I think it safe to estimate the average width of this forest belt to be nearly four miles. The Yellow Pine of the more northern mountains here gives place almost entirely to a form having longer and broader leaves. This Yellow Pine is the prevailing tree of the Chiricahua Mountains. The Arizona Pine, *Pinus Arizona*, is abundant in many of the cañons, but nowhere forms a preponderance of the forest growth. The Chihuahua Pine, *P. Chihuahuana*, a tree entirely unknown north of the Santa Catalina Mountains, is frequent at intermediate elevations between the Nut Pine, *P. cembroides*, and the Yellow Pines. On these mountains two species of White Pine come together, one, *P. flexilis*, being a northern species, while the other, *P. strobiformis*, is a southern species. The White Pines occur as scattered specimens or in groups of a dozen or more trees at the heads of the cañons and along the summit of the range. On no part of the mountains do they add materially to the forest growth. It is worthy of note that a number of groves of Arizona Cypress occur in the cañons on the western slope of this range.

The estimated forest area of the Huachuca Mountains is about thirty square miles. This is an irregular, broken area covering the slopes of the higher peaks and extending in places some distance down the cañons. Nowhere are the forests of these mountains as dense or valuable as those of the Chiricahua Mountains. A few restricted areas on the northern slopes are, however, fairly well timbered with the different species of Yellow Pine, namely, Yellow Pine, Southern Yellow Pine and the Arizona Pine. A scattered growth of Chihuahua Pine is found on these mountains just below the Yellow Pines. A few scattered trees of White Pine, *Pinus flexilis*, are found in the higher cañons. But one species of Nut Pine, *P. cembroides*, is found in this range.

The Santa Rita Mountains have a forest area of about thirty-five or forty square miles, centering about the high peak known as Baldy. These forests are of a denser growth than those of the Huachuca Mountains, but the same species are common to the two ranges, and in the same relative proportions. In relation to forest growth these two ranges are more alike than any of the ranges of southern Arizona.

Probably twenty-five square miles would represent the entire forest area of the Rincon Mountains. The forests here are unusually uniform, and consist almost entirely of the Arizona Pine, *Pinus Arizona*. It is interesting to note that the Yellow Pine, *P. ponderosa*, the prevailing tree on all the other ranges of southern Arizona, rarely occurs on these mountains. The Nut Pine, *P. cembroides*, is abundant, and the Chihuahua Pine is not infrequent.

The Santa Catalina Mountains are very broken and irregular, the highest point, Mount Lemon, reaching the altitude of 10,100 feet. The area of timber on this range is in the neighborhood of fifty square miles. All the higher portions are more or less thickly covered with Pine, Fir and Spruce. On the northern slope of Mount Lemon are growing the largest specimens of Douglas Spruce I have observed in the territory. At this locality, in a number of places, this species is the prevailing tree, many of the specimens being from five to six feet in diameter. Yellow Pine, *Pinus ponderosa scopulorum*, is the prevailing Pine. In these irregular, broken mountains are found all the species of Pines known to occur in the mountains of southern Arizona, with the possible exception of the southern White Pine, *P. strobiformis*.

The forest area of Arizona south of the Colorado plateau is, in round numbers, about 600 square miles. The total area of Arizona south of this plateau is about 75,000 square miles. From this it would appear that the Pine forest area

of southern Arizona is considerably less than one per cent. of the entire area. If we include the forests of Mesquite and other deciduous trees along the watercourses and in the lower parts of the cañons the total forest area would, of course, be slightly larger.

University of Arizona, Tucson.

## Foreign Correspondence.

### London Letter.

**PHAJUS COOKSONI.**—This is generally accepted as one of the most valuable plants that we owe to the skill of the hybridist, but its merits were never so fully revealed as by the specimen exhibited last week by the raiser, Mr. N. Cookson, of Wylam, Northumberland; this was a large mass carrying numerous large, healthy leaves and eighteen strong erect spikes a yard high, each supporting numerous rose and brown-purple flowers. I find this plant becomes unhealthy if kept in a tropical temperature, whereas in the intermediate house it is quite happy.

**ODONTOGLOSSUM CRISPUM LUCIANI.**—A first-class certificate was awarded to a beautiful variety shown under this name by Monsieur Linden, Brussels; the flowers were nearly four inches across, broad in the segments, white, shaded with rose and heavily blotched with purple-brown. The plant shown was small and bore only one small spike; there is, therefore, every prospect of its proving a still more valuable acquisition when cultivation has put some strength into its pseudo-bulbs and spikes. Connoisseurs voted it of first quality.

**EPICATTEYA MATUTINA.**—This is a new hybrid obtained by Messrs. J. Veitch & Sons from *Epidendrum radicans* crossed with *Cattleya Bowringiana*, the latter being the mother parent. The stems and general character of the hybrid are much more like those of the *Epidendrum* than the *Cattleya*, and the flowers, which are about two inches across, are yellow, tinged with vermilion, while in the three-lobed red and yellow labellum there is still less evidence of the *Cattleya*'s influence. Those who hold that prepotency is on the side of the female have strong evidence to the contrary in this hybrid.

**CIRRHOPE TALUM ROBUSTUM** is now flowering for the first time at Kew. It is a remarkable species, its leaves and flowers being much larger than those of any other species known, the former being about twelve inches by four inches and the latter four inches long, the width of the segments being correspondingly large; they are borne in umbellate clusters seven inches through, and they are yellowish green with a dark red oscillating lip. The species was first described by Mr. Rolfe in 1893 from a plant introduced from New Guinea. *C. graveolens*, Bailey, is a synonym.

**AN ORCHID SOCIETY.**—It is reported that Manchester Orchid fanciers are about to form a society in the interests of their cult and entirely independent of any other society. "An entrance fee of three guineas and an annual subscription of one guinea thereafter is suggested, but this and other matters are subject to approval of the meeting to be called at an early date. It is estimated that within a radius of thirty miles of Manchester the Orchid wealth of the country is centralized." If this society will limit its operations to such matters as the spread of a taste for Orchids, their cultural requirements, etc., nothing but good can come of it, but if it enters into rivalry with the Royal Horticultural Society and Kew with regard to nomenclature and certificates, it may prove more vexatious than useful.

**LATHYRUS SPLENDENS.**—In GARDEN AND FOREST, 1894, p. 274, I asked for more information about this Californian Pea, the "Pride of California." According to Mr. Orcutt, and on p. 294, I was told that it had not proved hardy in the northern states. Nor has it proved hardy or ever shown anything like comfort out-of-doors here, but about two years ago I planted a seedling in a bed of sandy soil in a low, airy greenhouse, and this has proved quite a success. It has thrown out hundreds of shoots with healthy pinnate leaves, and from all the strongest of them numbers of

flower-scapes are now developing. The first two racemes opened about a week ago and gave us a foretaste of what we are to expect about the middle of April. What a lovely plant it is! flowers like those of the Sweet Pea, but of the richest carmine-crimson which glows in sunshine. This is a first-rate plant for the greenhouse here; it is perennial, stands London fog and yields a large crop of richly colored flowers in early spring. A figure drawn from the Kew plant has been prepared for *The Botanical Magazine*.

**HIBISCUS MUTABILIS.**—The double-flowered variety of this Hibiscus is a worthy garden plant, which, however, is rarely seen in cultivation—in European gardens, at any rate. Mr. Cannell sent me some flowers of it a few days ago, describing it as a new Mallow, and by far the finest he had ever seen; they were three inches across, very double, and colored bright rose, flaked with white. Originally Chinese, the type has long been cultivated or become established in most parts of the tropics. The double-flowered form was first flowered in London about a hundred years ago, plants having been raised from seeds obtained from Jamaica, where it forms a tree fifteen to twenty feet high, with palmately lobed, green, hairy leaves four to six inches across; the flowers are borne singly on axillary peduncles, and they are white when first they open, changing to pink, and finally to deep red. There is a good figure of this double variety in Andrews' *Botanical Repository*, t. 228.

**NARCISSUS, ELLEN WILLMOT.**—This is a new variety or cross of the Ajax section which we owe to the skill of the Rev. G. H. Engleheart, of Andover, one of the most successful breeders of Daffodils. It has the form of Madame de Graaf or Empress, but is larger, and is remarkable for the width and shortness of its trumpet and its broad overlapping sepals and petals. The color of the trumpet is lemon-yellow, while the other parts are creamy white.

**NARCISSUS, SOUTHERN STAR,** is another new seedling from the same source. It is one of the Poeticus section, but the flowers are about four inches across, with broad overlapping segments of the purest white, and the shallow, spreading, eye-like cup is nearly an inch across, and colored bright orange-red, becoming paler toward the base.

**TULIPA KAUFMANNIANA.**—A first-class certificate was awarded to this plant last week, when it was shown in fine condition by Messrs. P. Barr & Sons, Covent Garden, and Messrs. Wallace, Colchester. It has a short stem, broad leaves and large erect flowers, the segments of which are oblong-obovate, forming a deep cup, their color yellow at the base, the upper portion white, suffused with rose-purple. It is reported that this species is being naturalized in the garden of Mr. L. de Rothschild at Leighton Buzzard, where it does well in the grass, and was in flower on March 23d. According to a correspondent in *The Gardeners' Chronicle*, it flowered outside in a garden in Salisbury on February 26th. For its introduction we are indebted to Mr. A. Regel, who found it in Turkestan some years ago. It appears to vary in the form and color of its flower-segments and also in its leaves, judging by the figure in Regel's *Gartenflora* and the plants shown by Messrs. Barr and Wallace. It belongs to Baker's *Eriobulbæ*, which has woolly outer bulb-coats and broad leaves. There is a hybrid between it and *Tulipa Greigii*, received by Herr Max Leichtlin a year or two ago.

London.

W. Watson.

A bulb is simply a large bud with close-packed, fleshy leaves or leaf-bases in which is stored an accumulation of starch, sugar and other concentrated plant food. As hibernating animals store up fatty matter before going to sleep for the winter so do bulbs store up surplus food and hide themselves under ground so as to go through cold and drought unharmed. Bulbous plants are developed in regions where there are sudden changes of temperature or of drought and moisture, and the great natural bulb fields of the world are found where it is very cold or very dry in winter, rainy and warm in spring, and blazing hot and dry in summer and autumn.—*F. W. Burbidge, M. A.*

## Entomological.

### An Enemy of Narcissus and Amaryllis.

**I**N *Merodon equestris*, the Narcissus Fly, we have one more addition to the numerous insects which have been introduced from the Old to the New World. Its first advent in the United States appears to have been many years ago, for Packard, in his *Guide to the Study of Insects*, published in 1869, states that the late F. G. Sanborn bred the flies from larvæ which were probably introduced by importers of Dutch bulbs. Since that time the pest does not seem to have become common in this country, at least it appears to have been rarely, if ever, noticed by economic entomologists, although gardeners may have had more experience with it than is generally known.

In the Agassiz Museum, at Cambridge, Massachusetts, there are larvæ of this pest and damaged bulbs of Narcissus which were received from a garden in Brookline, Massachusetts, in 1879. During the past year or two this same establishment has suffered more than usual damage from the ravages of the *Merodon*, which appears to have been present in more or less abundance every season since it was first noticed in the place nearly twenty years ago. At that time, besides various species and varieties of Narcissus, it was found to attack bulbs of *Vallota purpurea* and its varieties. Recently it has been found very destructive to many rare and beautiful *Hippeastrum* hybrids, formerly known under the generic name of *Amaryllis*, and it is probable that it will be found to attack other plants of the *Amaryllis* family, to which the Narcissus belongs. There does not appear to be any previous record that it has ever attacked anything except Narcissus. The pest has affected bulbs, both in the open air and in the greenhouse.

The damage is caused by stout brownish maggots which live within and devour the interior of the bulb, either entirely destroying its vitality or so weakening it that it fails to flower or gradually decays. These maggots when full grown vary in length from about half an inch or a little more when the body is in repose to about three-fourths of an inch when active and extended. The body is somewhat wrinkled, composed of eleven or twelve distinguishable segments, upon which are a few very minute hairs. The head is very small and armed with a blackish two-pronged hook used in scraping the bulb, and on the posterior or anal segment there is a conspicuous hard, shining, black double-tubed organ, and a little below each side of this is a short horn-like appendage. When fully grown the maggots usually leave the bulbs and enter the surrounding earth near its surface, or rarely remain in the remnants of the bulbs, and change to stout dark brown inert pupæ, about half an inch in length and retain some of the marks characteristic of the larvæ. From these pupæ flies emerge in the spring if the bulbs are out-of-doors, or during the winter if they are grown under glass. These flies are two-winged and bear considerable resemblance to the well-known bot-flies, or to the *Chrysanthemum* flies, *Eristalis tenax*, familiar on flowers in late summer and autumn. They might be mistaken for very small humble-bees, except for the fact that the latter have four wings, while the Narcissus fly has only two. These wings spread an inch or more from tip to tip and may be nearly clear or slightly smoky.

The body averages over half an inch in length and is sometimes nearly three-fourths of an inch long. The body-color is usually bluish-black, more or less densely covered with broad areas or bands of orange, yellow, brownish or blackish hairs. The color and proportions of these areas of colored hairs are so variable as to have caused the early entomologists to give *Merodon equestris* several other specific names, but it would not be profitable to consider these variations here. Most commonly the male has the fore part of the top of the thorax thickly covered with yellow-brown hair, a broad black band or saddle across the middle above the insertion of the wings, the posterior tip of the thorax and first two segments of the abdomen

covered with tawny colored hairs, and the remaining part of the abdomen with bright yellow-brown hair. A common type among the females has the thorax covered with bright ferruginous hairs, the fore and hinder parts of the abdomen covered with paler hair and with a black band across the middle portion. As in most flies, the eyes are very large, appearing to form the principal part of the head. They are black, and sparingly covered with microscopic brown hairs. In the males the eyes are near together, touching at one part; in the females they are well separated by a brown hair-covered ridge which broadens from the top toward the mouth parts. The legs are black or dark brown and more or less covered with black or gray or

cavity from which it only emerges when fully grown. Usually only one larva occurs in each bulb, but more may sometimes be found. It is not easy to detect infested bulbs until the maggots are nearly fully grown and the bulbs soften because of the ravages in the interior. Sometimes the entrance of the maggot may be detected by a minute brown streak showing where it entered between the scales at the top of the bulb.

Apparently, the first account of the Narcissus Fly is that given and figured by Réaumur in the fourth volume of his celebrated *Mémoires*, published in 1738. He there states that in November, several years previously, Bernard de Jussieu had given him a number of bulbs of Narcissus in which he found the larvæ, and from which he bred the flies. In 1792 Fabricius described it as *Syrphus equestris*, afterward placing it in the genus *Merodon*. On account of the variability of the insect it has received a number of synonyms, among which appear to be *Merodon flavicans*, *M. cinereus*, *M. Narcissi*, *M. ferrugineus*, *M. transversalis*, *M. constans*, *M. nobilis*, *M. tuberculatus* and *M. bulborum*.

The bulb growers of Holland have long known *Merodon equestris* as a serious foe to Narcissus-culture, and we have records of its presence in that country since before 1840. It is generally considered as having been introduced into Holland with bulbs from southern Europe, probably from Italy. Various accounts of its ravages appeared from time to time, and it was a frequent topic of discussion in meetings of Dutch bulb growers, who found it difficult to combat on account of its habits and little-known life-history. In *The Gardeners' Chronicle* for 1842 there is a figure and account of the insect by the late John Curtis, who wrote under the nom de plume of Ruricola, and this figure was reproduced in the same journal in 1877 and 1885. The same figure is given in Burbidge & Baker's monograph of the Narcissus, published in 1875. Among other important papers was one published by F. W. van Eeden, of Haarlem, in 1853, and one by A. C. Groenewegen, of Haarlem, in 1883. The latter advised watching for weak plants and those that failed to grow in spring, and their destruction if infested, and the searching for the chrysalids which might be found near the surface of the ground around the plants before they flowered.

In May, 1882, Mr. J. H. Krelage, the well-known bulb grower of Haarlem, sent specimens to Dr. J. Ritzema Bos, with the request to make a complete study of the pest, the results to be published at the expense of the association of bulb growers of which Mr. Krelage was president. The outcome was an elaborate paper, with two plates of figures, entitled "La Mouche du Narcisse," published in *Archives du Musée Teyler*, series 2, vol. ii., part 2, Haarlem, 1885, and published also in the Dutch language. In this exhaustive monograph the author gives the results of various experiments in attempts to find means to combat this insect. One, at first thought to be efficacious, was very simple, and consisted of the immersion of the bulbs in water for eight days before planting, this seeming to kill or drive out the larvæ. Further experiments, however, showed him that immersion could not be relied upon to kill the maggots, and this conclusion is verified by Mr. Krelage in the *Revue Horticole* for 1889, who states that the method most generally followed with success is Groenewegen's plan already referred to. If the spring is cold and wet when the flies are emerging from pupæ a large proportion of them may die without laying eggs, and so there are periods of comparative immunity, but after a few favorable seasons they again become abundant.

In Brookline, Narcissus-bulbs in a warm dry rockery have been found much more liable to destruction than those growing in low damp ground, and especially among grass. Also, *Hippeastrums* under warm dry cultivation have been found much more affected by the pest than those grown under cool and moist conditions. Among these beautiful and often high-priced flowers the *Merodon*

Fig. 18.—*Merodon equestris*, a Narcissus pest.—See page 154.

Anal segments of larva, enlarged. 9. Pupa, natural size. 10. Section of Amaryllis bulb, showing destructive work of larva and hole made for exit.

tawny-colored hair. The generic name of *Merodon* was given on account of a small tooth-like projection on the lower end of the femur of the posterior leg.

So far as known only one or two eggs are deposited at each plant, and the female appears to deposit them near the base of the leaves above ground in May or June, when the plants are out-of-doors. Upon hatching, the young larva is said to work its way into the bulb by burrowing between the scales, and once in its heart, it makes a large

equestris has proved itself capable of doing much damage, and cultivators should be on their guard against it.

The figures of *Merodon equestris*, on page 155, are from drawings by Mr. C. E. Faxon.

Jamaica Plain, Mass.

J. G. Jack.

## Cultural Department.

### Seasonable Notes.

AT this season every inch of available greenhouse bench and shelf room is in use, and it is difficult to find space for all the plants when potted or boxed. Every private establishment should have a number of cold frames, as they are preferable to greenhouses for growing many plants during the next few weeks, and the stock can be more readily hardened off and brought into good condition for planting outside.

Bedding plants at this season take up much space. Many flowering annuals are grown to use in the perennial borders and to grow for cut flowers. Our earliest Asters are now of good size in boxes in a cool frame. We usually plant these out about May 10th. Queen of Earlies and Comet are used for our first sowing, and we make successive sowings of these until the first week in July. Stocks, we find, do better grown in small pots; the possibility of breaking their roots when planting out is thus avoided. Zinnias are among the best annuals for cut flowers; while stiffer in appearance than Asters, they bloom continuously. Seedlings of these and various other annuals are now pricked off into boxes or frames. Geraniums were recently transferred to a cool frame from which Violets had been removed, and will be kept moderately close for a few days until warmer weather is assured. Coleus require strong heat, and a few sashes filled with warm stable manure and leaves provide a suitable place for these plants. Alternantheras root quickly and revel in such quarters. Carnations for summer blooming are now forming roots in three-inch pots in a cool frame. These will be planted out early in May. Winter-flowering Carnations in boxes can also be gradually hardened in a similar way. We look over the plants once a week and do any necessary stopping. Thus far there have been no signs of rust on our young stock.

Considerable space has recently been taken up with plants grown for use at Easter, and not a little judgment is necessary to bring them into flower at the right time, owing to the lateness of the season and vagaries of weather. We have this year tried a few Cape Cod grown bulbs of *Lilium candidum*; they are superior to the French bulbs we have usually grown, and there seems to be no reason why so many of these bulbs need be imported annually if they can be raised and sold at corresponding prices here. The sandy soil on Cape Cod and some other places is peculiarly suited to the growth of good clean bulbs of *L. candidum*. We plant out our forced stock after the flowers are cut, and if undisturbed for a few years and generously treated they give splendid spikes. *L. Harrisii* and *L. longiflorum* have shown a larger amount of diseased plants than ever before. Some commercial growers report that from fifty to seventy-five per cent. of their stock is diseased, thus entailing a serious loss. It seems imperative for large buyers of these bulbs to visit Bermuda during the flowering season, and see that those from whom they buy bulbs have clean stock. The disease undoubtedly comes in the dormant bulbs, and is not due to subsequent treatment. As soon as *Spiræas* (*Astilbes*) have finished blooming they are planted out in rich, rather moist, land, and make capital forcing clumps after being rested a year. The Crimson Rambler Rose has proved a decided acquisition as a flowering plant at this season. We grew a few plants from cuttings rooted late last spring, and flowered them in seven-inch pots, bending the shoots over in the form of a hoop. They all broke and flowered splendidly. This Rose is reliably hardy here, and survived outdoor treatment perfectly, while many hybrid Perpetuals were killed-back quite severely. We have some young plants now in two and a half inch pots, which will be grown along in pots for flowering next Easter.

Cannas continue to make rapid strides in popularity as is evidenced by the great numbers cultivated everywhere. But there is danger that they will become so common that popular fancy will turn to some other novelty. They are not sufficiently appreciated for winter flowering in pots. We have tried about twenty of the leading sorts this season, and the majority have been in flower since Christmas and are still loaded with spikes. Among the best varieties for pots are Queen Charlotte, Madame Crozy, F. Vaughan, Eldorado, Paul Bruant, Alphonse Bouvier, Gloire de Montet and General De

Mirabel. Our stock for bedding purposes are in four-inch pots, in a Carnation-house temperature. Tuberous Begonias are capital bedding plants for partially shaded locations, where they can be kept well watered. Our tubers were recently started in boxes of light sandy loam in a frame. Water needs to be given sparingly until they are well started into growth. Fibrous-rooted Begonias are beyond question among the very best winter-flowering plants, and no greenhouse is properly furnished unless it contains some of the leading sorts. We have just potted off a lot of these plants into small pots for flowering next winter, and there is still time to root and grow on good plants if cuttings have not yet been inserted. *B. Haageana erecta*, *B. semperflorens gigantea rosea*, *B. nivea* (a beautiful white variety) and Paul Bruant are among the most attractive sorts we have grown, but many more are beautiful. Of newer sorts we have two of the *Semperflorens* type which promise to be fine, Goliath and Mastodonte. The variety Gloire de Lorraine, already several times referred to in GARDEN AND FOREST, is sure to become popular.

Pelargoniums of the regal and show sections are now flowering profusely. It is surprising that so few private places grow these plants; a bench of them in bloom presents a striking appearance. They are mostly grown in six and eight inch pots and require plenty of water, frequent doses of liquid-manure and a light fumigation every ten days for green aphids. They like a partially shaded, cool, airy house. We find them useful for decorative purposes, and we drop a little floral gum in the centre of each flower to hold the petals together.

Now, when there is a pressure of work in all departments, the compost-heap is apt to be forgotten. Our Carnation compost was prepared last fall; it will be turned over shortly to give it a thorough mixing. We usually plant our Roses out in benches early in June, and have turned over the compost-heap for these recently and added some finely ground bone. If compost-heaps have not already been prepared they should be attended to at once.

Taunton, Mass.

W. N. Craig.

### Some Cool-house Shrubs.

WITH the arrival of spring we are again reminded of the wealth of good material in hard-wooded plants adapted for cool-house culture, and which have, in this country at least, been comparatively neglected in recent years. The plant-buying public becomes more discriminating each season, however, and a greatly increased demand for the few species of hard-wooded plants now offered for sale proves that interest in them is awakening.

The few Acacias now grown, mostly *A. pubescens*, *A. armata* and *A. Riceana*, deserve to be more generally known, and these three species form a good beginning for a collection of these charming plants. They are as easy to manage as *Azalea Indica*, the chief difference in treatment being that Acacias require rather more pruning to make shapely specimens.

Azaleas can be successfully flowered in a living-room without previous preparation in a greenhouse. After blooming the plants should be repotted, if necessary, and when the weather becomes warm, for example, about May 1st, the pots should be plunged out in the garden. They should be watered thoroughly every day during dry weather, brought in before frost in the fall and stored in a light, cool room. Those I have in mind were kept in a light attic where the temperature was probably just above freezing during cold weather. They should be brought into the warmer rooms of the house as their flowers are wanted. From plants thus treated by a neighbor a bountiful crop of flowers was produced, of good size and substance.

For several seasons past it has been shown by commercial growers that species of *Ericas* can be grown as well in this climate as in that of Europe, and while all species may not prove equally satisfactory, there are enough of free-growing ones to add greatly to the beauty and variety of the cool greenhouse at this season. Among the easiest to manage are *E. hyemalis*, *E. Wilmoreana*, *E. persoluta* in its various forms, *E. hybrida*, *E. melanthera* and *E. præstans*. These give a succession of bloom from late autumn to early spring. Outdoor culture is the most satisfactory for these plants during summer, providing they are given plenty of water in dry weather. There is less danger from red spiders under these conditions than when the plants are kept in the greenhouse.

The *Boronias* and *Eriostemons* are also welcome additions to the cool house in spring, and do not occupy much space before reaching the blooming size. While their flowers are not very large, those of the *Boronias* have the added merit of being fragrant. The brown-yellow flowers of *B. megastigma* in par-

ticular exhale an exceedingly agreeable fragrance. *Daphne Indica* is an old plant that has become rare in greenhouses, where it was plentiful twenty years ago, though less meritorious plants occupy its place. The best specimens of this plant that I have seen were planted out in a Camellia house, and received precisely the same treatment as the Camellias. As a pot-plant it is not always a success, as it is easily injured by careless watering during the winter.

The Indian *Rhododendrons* also deserve more attention. Some of the species and varieties are seldom out of flower. The white and pink varieties are among the most beautiful, and bear large flowers, many of them fragrant.

*Rondeletia gratissima* (also known as *Rogiera*) and *R. thyrsoides* both deserve a place in the cool house, since they are easy to grow and quite free-blooming. These evergreen shrubs bear terminal or axillary trusses of flowers, as the *Ixoras* do. After flowering they should be cut back to keep them in shape, and potted in good loam, with free drainage. *Chorozema cordatum* should also be included in the available list. It is easy to manage and decidedly attractive when in flower. The long and graceful shoots are laden with pea-shaped flowers of orange and red, and give a cheerful touch of color to the house. This plant also should be pruned after the blooming season, and is seldom troubled by insects unless it is grown too warm, when it is liable to be attacked by red spider.

Holmesburg, Pa.

W. H. Taplin.

### *Erythronium grandiflorum* and Related Species.

IN the *Botany of California*, published in 1880, *Erythronium giganteum* and *E. grandiflorum* were confused. Sereno Watson, in his *Revision of the American species of Erythronium* in 1891, corrected this mistake, but dealers and botanists had followed the older authority so long that it has been hard to overcome the error, and nearly all of the bulbs grown or sold by dealers as *E. grandiflorum* are really *E. giganteum*.

*Erythronium giganteum* is a strong-growing species, with the flowers one to sixteen in a raceme, and the leaves richly mottled in green and mahogany-brown. The flowers are straw-colored, with orange centre. The true *E. grandiflorum* has light green leaves entirely destitute of mottling, and its flower is oftener solitary. In its different forms *E. grandiflorum* has the widest distribution of any western species. It is found in the higher Cascades in Oregon and Washington, and in the Blue Mountains of eastern Oregon, in the Pine forests of eastern Washington, in northern Idaho and thence east to the Rockies and along that range to Colorado.

I know of three forms of this species. In the higher Cascades of Oregon and Washington there is an alpine form with light yellow flowers. It was this form and *Erythronium montanum* which were so beautifully represented in the recent illustration in GARDEN AND FOREST (see vol. ix., p. 504). In the Blue Mountains in eastern Oregon is found a bright yellow form, the only really yellow *Erythronium*. In the Pine woods of eastern Washington there is a form with pure white flowers with greenish yellow centres. In this the flowers are very large, and the narrow segments are closely recurved.

*Erythronium montanum*, an alpine species of the higher peaks of the Cascades, also has unmottled leaves and pure white flowers with yellow centres. In this the leaves are rounded at the base, a character which readily distinguishes it. In its high mountain home the seasons are very short, and it is wonderful how soon after the snow has melted its beautiful flowers will expand, and how much cold and what hard conditions such frail-appearing creations will endure.

In the Sierra Nevada, from the north to Tulare County, there is another species with unmottled leaves growing in high altitudes. In this the leaves are a dark purplish green, and the flowers borne in a crowded raceme. The flowers are white, with an orange centre, and are suffused with and soon turn pinkish purple. This species I have identified as *Erythronium purpurascens*, although Mr. Watson described the latter as having mottled leaves.

These three species then are the only western Dog's-tooth Violets with unmottled leaves, and, although varying considerably in style, stamens, etc., are very much alike in habit and growth. As garden plants they are not nearly as satisfactory at Ukiah as the mottle-leaved species, perhaps because I have not yet given them just the right position and shade. The trouble is that they flower too soon after they come through the ground and have no length of stem. I have tried giving extra shade, with some improvement, but think I will have to find a colder position for them. There is no trouble with any other species in that regard. Again, I found that

*Erythronium montanum*, following the habit in its mountain home, does not come up till after it becomes too warm here for its proper flowering. I have the same fault to find with *E. purpurascens* from high altitudes, although the same species from a lower altitude is now (April 1st) in flower.

What is a fault here might prove to be a recommendation in the colder climate of the eastern states or northern Europe, and I am inclined to think that the true *Erythronium grandiflorum* in its various forms would do splendidly there.

Ukiah, Calif.

Carl Purdy.

### *Lilium Harrisii* and the Electric Light.

AT a recent meeting of the Horticulturists' Club of Cornell University, M. G. Kains presented notes of experiments with the Easter Lily. As to the effects of the electric light in its cultivation, he said that the bulbs were potted the middle of October, plunged in a solid bed late in December, and the electric light turned on January 1st. A globeless arc lamp was used. It burned from 5 P. M. until 6 A. M. for the following four months. The bed was divided into three sections. The first was exposed to the full glare of the naked light; in the second, the light passed through a large pane of glass which cut out some of the ultra violet rays, but did not impede the passage of the light; the third section was separated from the light by a black canvas curtain, which was drawn across the bed each night before the lamp was lighted. When the light was first turned on, the plants were of uniform development, but in six weeks changes appeared in the foliage, which gradually became more pronounced. The plants in the lighted sections grew very tall and spindling, had long peduncles, narrow and sallow green, very much curved leaves far apart on the stems. These effects were most apparent under the naked light. The plants in the unlighted section were more robust; had deep, glossy green leaves, were more stocky, less subject to disease, and, on the whole, more evenly developed. After the buds were formed these differences did not become more pronounced, but the buds under the naked light soon began to show a dark brown streak on the surface most exposed to the direct rays from the lamp, and this burn increased as the buds grew and expanded into blossoms. The seared petals were much more curled than is ordinarily the case with healthy blossoms, and the stripes of brown were in some cases a quarter of an inch wide on each of three petals. No such trouble was experienced with the plants in the light which had passed through the pane of glass. The earliest flowers appeared on plants in the naked light, and in this section they lasted on the average nine days. Four days later the plants in section two flowered, and lasted here nine and a half days. The plants in the unlighted section were nine days later than those in section two in coming into blossom, but the flowers, though slightly smaller, lasted eleven days and were more robust. The flowers in the lighted sections, like the plants which bore them, were spindling, but not unsightly, excepting those which were burned.

A plant with two remarkably evenly developed stems was taken from the unlighted section, and so placed that the curtain could be drawn between them, the one stem being in the unlighted section, the other among the plants behind the pane of glass in section two. A second twin-stemmed plant was also taken from the unlighted plot and placed in the naked light, but the larger of the two stems was covered each night with a tube of manilla paper to exclude the light entirely. In each case the stem in the light blossomed a day before the other stem. Some other plants of uniform development were marked, and a part of them removed to the lighted sections, the others being left in section three. The former bloomed seven days before the latter, the last blossom in the former group being three days earlier than the first blossom in the latter group. The blossoms were perfectly healthy and lasted as long as those in the unlighted section. From these experiments it is concluded that it will probably pay commercially to use electric light in cultivating *Lilium Harrisii* when the buds are an inch long, in order to hasten their expansion, and that the light must pass through glass to avoid burning the petals.

Cornell University.

*Sternbergia Fischeriana*.—This is a spring-flowering species of the well-known Winter Daffodil, and as it now appears in the border is a noticeable flower, even though it comes in Narcissus time, when yellow flowers are becoming plentiful. *Sternbergia Fischeriana* differs from the fall-flowering *S. lutea* in having much broader leaves, smaller flowers of the same rich yellow color. The peduncles are short and the flowers are borne above the leaves, which as yet are only slightly de-

veloped in height. The plant flowers freely, each bulb producing several blooms. The Sternbergias are all valuable bulbous plants in any garden and are perfectly hardy, even the leaves of *S. lutea*, which are in evidence all the winter, and only ripen at this season, being unaffected by the rigors. That they are not more grown is probably owing to their need of a special position in the border, which they do not always find. As *S. lutea* now ripens it requires a position where it will be fairly dry, and a warm place where it will be well roasted in summer. In such a position, in rather heavy soil, it has never disappointed me; and it starts in due time in the late fall and blossoms profusely, and even multiplies. The large-flowered *S. macrantha*, which follows this species in flower, evidently requires the same kind of location, for several clumps planted in other conditions here have as yet failed to do much in the way of flowering, though the leaves are now prominent enough.

Elizabeth, N. J.

J. N. G.

**Carnations.**—These plants were never finer than they now are in the houses of William Nicholson, at Framingham, Massachusetts. Eldorado is perfection here and unique in its class. It is a fragrant picotee with yellow ground and red-edged petals. The demand for fancy striped varieties is very properly increasing every year. Della Fox has not given entire satisfaction. It was expected to supersede Daybreak, but there seems to be room for both of them, and especially for Daybreak as it is grown by Mr. Nicholson, and Mr. Tailby, of Wellesley, has Della Fox at its best, and this is remarkably good. Hector, where it succeeds, is a superb variety, but florists about Boston are looking for a better scarlet than Portia. A very high opinion is given of Tailby's new scarlet. As seen with him it does not appear to have a fault. In strength of stem and size and shape of bloom it is Daybreak in every particular except color, while it is better in constitution and fully as free. Jahn's scarlet has first-rate points, but it fades quickly, and the same may be said of Nicholson's Camp Fire, which has proved a splendid summer bloomer.

**Calla Elliottiana.**—Mr. Watson's reference to the yellow Callas reminds me that I saw just one hundred seedlings a few days ago at Mr. Tailby's, all from one head of seed; 104 seeds germinated and four plants died. From the three original plants raised two years ago Mr. Tailby has raised twenty by offsets and division. Dividing is hazardous, and one fine plant was lost through this method. That they need some moisture during the winter and tolerable warmth is the experience on this side. Hybridizing with our common Arums has been tried, and also with the Little Gem Calla, but evidently without advantage. What seems the most likely and possible cross will be tried this season with *Richardia alba maculata*, a species in appearance very similar to *C. Elliottiana*.

## Correspondence.

### Notes from Cornell University.

To the Editor of GARDEN AND FOREST:

Sir,—A number of interesting things are now going forward in the Horticultural Department at Cornell University. Perhaps the most unique venture is the plan to grow this year all the kinds of annual flowers. These plants have been given very little systematic study in this country, and their botanical classification and direction of evolution are very little understood. An excellent piece of land has been set aside for the test, and all the tender species have already been sown in flats in the forcing-houses. The greater part of the kinds, however, will be sown directly in the field. J. M. Thorburn & Co. have supplied over 800 kinds of flowers to this test, and it is the desire of Professor Bailey to receive seeds of any varieties of annual flowers which seedsmen or others may wish to have tested.

The Dahlia test is to be continued this year. An excellent plot of ground is available for this purpose. Seeds and tubers of a number of the wild species have been received from Mexico, and these are already growing under glass. It is not expected that this Dahlia test is to comprise all the varieties now on the market, but it is probable that over 500 kinds will be grown. The American Dahlia Society will send a committee to inspect the plantation this year.

Just at present a fine collection of Geraniums is in bloom in one of the houses. About 430 varieties are in flower, distributed among the various groups, as Bedding Geraniums, Ivy-leaved Geraniums, Show and Tricolor Pelargoniums, Rose Geraniums and the like, Professor Bailey is taking great

interest in Pelargoniums just now because the group is a most fertile one in which to study many problems connected with the evolution of plants. He is in correspondence with persons at the Cape of Good Hope, whence he hopes to secure some of the wild types, and he will look up the subject abroad during the present summer.

A very large collection of *Ixias* is just now passing out of bloom. Over fifty varieties of Mignonette are now in full glory, and a number of experiments are going forward respecting the influence of certain conditions upon fragrance.

The second crop of Strawberries is now passing. The first crop was off about a month ago. The larger part of a house, twenty by thirty feet, has been devoted to the Strawberry, and the most satisfactory results have been secured. The first crop averaged six to eight perfect berries to the pot, and the first quart sold (early in March) for \$2.00. So far, the Beder Wood has given the best results, although the color is too light for an attractive berry. Van Deman is now in crop, but, although a perfect flower, it seems to need extra care in pollination. The handsomest berry in the house is the Hunn, but its lateness debars it from winter cultivation.

An extra effort is being made to determine the causes of unsatisfactory results in the growing of Mushrooms. In order to study the question under the best conditions an ideal house was built last summer, with stone sides and iron roof, with an inside space of about thirteen by eighty-two feet. Something like a dozen methods of growing Mushrooms have been tried during the winter. Some of them have resulted in entire failure, and others have given excellent results. One of the curious things in connection with the experiment is the fact that the wettest beds—even those which are almost soaking wet—have, so far, given the best results, although this seems to be contrary to general experience.

Ithaca, N. Y.

### An Orchid Scale, *Aspidiotus biformis*.

To the Editor of GARDEN AND FOREST:

Sir,—The scale which I described as *Aspidiotus biformis* was discovered on June 9th, 1892, on a plant of *Cattleya Bowringiana* at Hope Gardens, Jamaica. On July 7th of the same year I found it again on an Orchid at the Kingston (Jamaica) Flower Show. In December, 1892, Dr. Henderson found a variety of the same scale on *Odontoglossum grande* at Kingston, Jamaica. In the meanwhile Mr. Hart had detected it in the Royal Botanic Gardens, Trinidad, on *Oncidium sprucei*; later he found it also on *Epidendrum*. Occurring thus on several genera of cultivated Orchids, I had expected that the scale would before long be brought to the United States, though no specimens had yet been seen except from the West Indies. This expectation has now been realized, but, fortunately, the scale has been prevented from landing by Mr. Craw, who found it on a vessel from Central America arriving with Orchids at San Francisco. The specimens have been transmitted to me, but the exact locality where the Orchids were obtained is unknown, nor do I know the species of Orchid.

The female scale is small and round, nearly flat, of a reddish brown color, quite dark; the male scales are very small and inconspicuous, elongate in form. By the shape of the male scales, especially, the insect is readily distinguished from *Aspidiotus ficus*, which it somewhat resembles. The microscopical characters are very distinct; the lobes are very distinct, and in the Central American specimens I find four groups of ventral glands, rather scattered, four or five glands in a group. The margin cephalad of the third lobe presents three low minutely crenate elevations, after which comes a conspicuous notch, and beyond this are more minute crenations.

It is very probable, of course, that this scale will gain access to some of our hot-houses, where it may become troublesome on choice Orchids.

Mesilla, N. M.

T. D. A. Cockerell.

### Plants at Wellesley.

To the Editor of GARDEN AND FOREST:

Sir,—The greenhouses on the place of H. H. Hunnewell, at Wellesley, Massachusetts, are just now especially interesting for plants which are intended for summer decoration. Pelargoniums, Show Geraniums, Fuchsias, Roses, Spiræas, Astilbes, Indian Azaleas and many other plants in pots are pushing vigorously forward.

*Cytisus Andreanus* in bloom is especially beautiful; the large yellow flowers, with reddish brown standards, are very showy. It must be a splendid plant for shrubbery borders where it is hardy, as, for example, in our southern states or in California, where it ought to flourish. A bush of the European

Gorse, *Ulex Europæus*, an allied plant, is not to be despised. It at least reminds Old World gardeners of home. A few *Imantophyllums* remain in bloom. One of the best is from a set of seedlings sent here for trial by Messrs. Veitch, of London. It is much superior in size and color to the type. A well-flowered bush of *Franciscea confertifolia*, with salver-shaped flowers of light and dark blue, is very attractive. It is an interesting specimen, and one of the good old plants of which, in this age of commercial rotation, we see fewer every year. *Gloneria* (*Psychotria*) *jasminoides* is another of these. It is a bush of slow growth, and this specimen is about six feet high and probably twenty years old. It belongs to the *Rubiaceæ*, and its opposite leaves and umbellate arrangement of narrow-tubed four-limbed corollas remind one of the more common *Ixoras* which belong to the same order. A grand specimen of *Lomaria gibba* has just furnished itself with a new set of fronds—the second set this winter. It has a clear stem three feet long and a spread of six feet—a specimen such as one seldom sees. Here, too, is an extensive collection of hybrid *Hippeastrums*, new and old, and some of them are carrying gorgeous flowers. *H. vittatum*, though one of the oldest, is among the best. *Olympia* has blooms of orange-red seven inches in diameter, and *H. Mastersi*, though small, is free-flowering, with early deep red blooms. I have a batch of seedlings from a cross between *H. Johnsoni* and *H. Mastersi*, and although *H. Johnsoni* is the seed parent the majority of the seedlings, as far as they have flowered, show a decided leaning toward the pollen parent. As *H. Mastersi* is earlier than *H. Johnsoni*, does this account for the preponderance of the former among the seedlings which first show flower?

Wellesley, Mass.

T. D. Hatfield.

### Notes from Germantown.

#### To the Editor of GARDEN AND FOREST:

Sir,—Our early-flowering shrubs have done uncommonly well this spring. Such plants as *Jasminum nudiflorum* and *Lonicera fragrantissima* were very full of flowers, and none of the buds were injured by cold. *Chimonanthus fragrans* flowered in a desultory way with us, beginning with a few blossoms in February, then came others in March, and I notice a few opening to-day, as late as the 15th of April. I am told that the flowers of *Chimonanthus* expand about Mobile in January, and that it bears seed there freely. Next to the three shrubs mentioned, *Daphne Mezereum* flowered, a much-neglected plant and hardy several degrees north of this latitude; then followed *Cornus mas*, an excellent shrub because it continues in flower a long time, and as I write, on the 15th of April, the flowers are still opening rapidly. Besides this, it is beautiful in fruit and foliage. *Prunus Davidiana* followed the *Cornus* closely; *Forsythia suspensa* is now in full display a little in advance of the variety known as *viridissima*, and with larger and lighter-colored flowers. Our native Spice-wood is in full bloom; *Magnolia stellata* is in its prime, and the flowers of *M. Kobus* are beginning to open a little in advance of those of *M. conspicua*, which is itself a day ahead of *M. Soulangeana*.

I have rarely seen our Swamp Maples so beautiful as they are now. Some of them are a perfect mass of brilliant red flowers. There is a great difference in the color of the flowers on individual trees, and this point ought to be considered in propagating varieties. The flowers are dropping from the Elms and Soft Maples, and as no frosts have occurred since they opened, we shall undoubtedly have an abundance of seed.

Germantown, Pa.

Joseph Meehan.

### Recent Publications.

*Diseases of Plants Induced by Cryptogamic Parasites.* By Karl Freiherr von Tubeuf, translated by William G. Smith. Pp. xv., 598, 8vo. with 330 figures. Longmans, Green & Co., London and New York.

This treatise is one of the best general works on fungi which cause diseases of plants which have yet been published. The original German edition appeared only in 1895, and it is unusual for an English translation of so large a book to be prepared in so short a time. This is, perhaps, due to the fact that Dr. Smith, the translator, was at one time a pupil of Dr. von Tubeuf, and was on that account the better able to present his views to the English-speaking public. The translation follows the original closely in most respects, but in some cases, as in the accounts of the genera *Exoascus* and *Gymnosporangium*, the subject has been revised and extended by the author so

as to embody the results of recent investigations. In form the treatise is encyclopædic, a general enumeration and description of all the principal parasitic fungi which are of interest to the vegetable pathologist being prefaced by short chapters on the nature of parasitism, the effects of fungi on their hosts, their relation to the substratum, and similar topics on which the non-professional reader needs information before proceeding to the consideration of special fungi. There is also a short account of preventive and combative measures, and two chapters on symbiosis. The author has shown good judgment in his management of these topics, and, although brief, is clear, and he has avoided entering upon lengthy discussions of questions on which authorities differ.

By far the larger part of the book is devoted to descriptions of different species of parasitic fungi, including not only European fungi, but many species from North America and other parts of the world. The author has summarized the very large number of papers relating to fungi which cause diseases of plants which have appeared in recent years, and few books on a subject in which new facts are brought out monthly, and almost daily, have the appearance of being so well up to date as the present work. The fungi are arranged by their orders, beginning with the lower, and under each order are given the more important genera and species pathologically considered. Then follow chapters on pathogenic slime-fungi, bacteria and algæ. The pathogenic bacteria are very summarily treated, but the plan of the author evidently did not require a full treatment of these forms, which, at the present day, are usually relegated to special treatises. At the end are a very convenient index of parasites and an index of host-plants. We know no book on the subject which presents so attractive an appearance. The text is unusually clear and well arranged. The numerous figures are, in nearly all cases, well executed. Those taken from other works are well selected and do not have the time-worn look often found in treatises on this subject, and there are also many original and characteristic habit-pictures. The figures in the translation, however, are not so well executed as those in the German edition. In short, the book is one which should be in the working library of all students of economic fungi.

As a supplement to the manual entitled *Vegetables under Glass*, Mr. Henry Dreer has just issued a similar work on *Vegetables Grown in the Open Air*. The plants are grouped according to their botanical affinities, an arrangement which has many advantages, but which we have never before seen followed in a manual of this sort. This study of plants which are botanically related affords an opportunity to give certain descriptions of the general characteristics and cultural requirements of the entire group, and the specific differences can be explained in connection with the general resemblance which they bear to each other. The subjects of drainage and fertilizing, irrigation, spraying and storing the crops are treated in a practical way, and the cultural details contain abundant quotations from practical growers upon specific points. Altogether, it is a good little book, and the same may be said of *Grasses and Clovers*, another one of this series which is generally known as Dreer's Library. This is a little handbook on forage crops, with a chapter on lawn-making and lawn management. We have been trampling grasses under our feet all our lives, and yet perhaps there are few plants about which we really know so little. This little treatise will be found useful to any one who is beginning the study of this interesting family. But besides the Grasses, leguminous crops are made the subject of a discriminating essay, and farmers everywhere are urged to experiment with the Cow Peas, the Clovers, Vetches, Tares, Beans and other plants of this family on account of their special power of transferring the free nitrogen of the air to the soil and thereby enriching it with the most expensive element of plant-food. These manuals cost only twenty-five cents each.

## Notes.

*Magnolia stellata* was in full flower in the vicinity of this city on the 15th of April. The fine specimen which we figured on page 195 of vol. ix. was a mound of snowy bloom more than twelve feet in diameter.

Two little girls near Croydon, England, recently died of acute inflammation of the stomach brought on by eating young growths of the common Privet. Children should be cautioned against eating the leaves or fruit of any plant with which they are not familiar.

Pots of fruiting Strawberry-plants were an attractive Easter specialty in a fruiterer's window on Broadway last week. The foliage was fresh and luxuriant, with three or four large highly colored ripe berries and a few immature ones. The plants sold for \$1.50 to \$2.50 each.

The white form of *Chionodoxa Luciliæ* seems to grow as strongly as the type, and makes a grateful contrast with it. The white form of *C. gigantea* is rare, but it is a sturdy and desirable plant, and we may hope that within a reasonable time white *Chionodoxas* of all the species will be comparatively abundant.

Several large growers of Lilies for the Easter market make complaint in the *American Florist* that the bulbs of *Lilium Harrisii* which are grown in Bermuda are proving generally diseased. They all agree that these bulbs could be satisfactorily grown in our southern states, the only trouble being that Americans are disinclined to wait for profits. It would require two years at least before any crop could be marketed.

The first tree with conspicuous blossoms to flower this year in the Arnold Arboretum was the north China Peach, *Prunus Davidiana*, which was fully out ten days ago and has been extraordinarily beautiful. This tree is perfectly hardy, but the flowers are often killed by frost after the buds begin to swell, and during the ten or twelve years that it has inhabited the Arboretum it has only once or twice before flowered as profusely as it has this spring, and although producing more or less flowers every season it has not borne fruit yet in the Arboretum. *P. Davidiana* ought to be better known as an ornamental tree, as it flowers before any of its kind, and the pale pink petals, although not as large as those of some forms of the cultivated Peach, are exceedingly attractive.

Maple wood has a distinct and positive value for flooring which no other hardwood which is workable possesses. Its hardness and smoothness give it power to endure the severest wear; it has a light and attractive color, and it can be cleaned as easily as Maple. It has hitherto been abundant enough to meet the growing demand in every part of the continent and the requirements of the large export trade. Nevertheless, since only a part of the tree is utilized, the waste of the lumber is great, and the best hard maple, which is found in the lower Michigan peninsula and in Wisconsin, is disappearing more rapidly than even the Pine did, because, as a rule, good Maple land is good farming land. The time seems to be coming when the supply will be depleted, and the *Northwestern Lumberman* is, no doubt, right when it complains of the reckless competition under which this valuable product is sacrificed.

Different species of *Swainsonia*, particularly *S. Greyana* and *S. galegifolia*, which is largely grown for cut flowers in this country now, are plants which are greatly dreaded by the stock growers in Australia. Chemical analysis does not show any toxic principle in the plants, and yet when sheep and other animals eat them they acquire a habit for them and will eat nothing else, their brains seem to become affected, they never fatten, and finally die. Sheep addicted to this habit are known as "Indigo eaters," and they separate from the flocks and wander about listlessly. A case is recorded where horses hobbled for the night at a place where *Swainsonia* was growing were difficult to catch the following morning, their eyes were staring out of their heads, and they pranced about against trees and stumps. Two out of nine died the second day after, and five others had to be left in the camp, for when driven they would suddenly stop, turn round and round for a time, then fall down, rise again and repeat the performance. No experiments as yet give any reason for the complicated effects which this forage has on stock, but there certainly is much testimony to the fact that it causes a sort of madness which induces creatures who feed upon it to attempt to climb trees or commit other eccentricities. Baron Mueller believed that *Swainsonia* possesses the deleterious properties attributed to it, and he publishes this view in the Transactions of the Royal Society of Victoria.

Fresh figs are hardly known in northern markets because the fruit is so perishable. They ripen when the weather is hottest and can be handled only by experienced persons. It is costly work, too, to prepare the fruit for distant marketing. The trees need to be picked over carefully every day, and this involves much labor; rainy weather occasions loss by packing, and the acrid juice of immature figs eats into the fingers of the pickers and packers. It is necessary to pick them while still firm, which is a misfortune, for although they become quite edible when soft they lack the fine quality of tree-ripened fruit. In their best condition they will hardly keep thirty-six hours at ordinary temperatures, but, of course, they can be kept much longer in a cold temperature, so that with rapid refrigerator transportation the shipment of figs from the south might become a business of importance. Next to fresh figs canned figs are the best, and there is no reason, except for the larger quantity of sugar required, why figs should not be grown and canned as cheaply as peaches. The figs are sometimes peeled before canning, and this is supposed to increase the delicacy of their flavor. Usually, however, they are cooked unpeeled and with the stems on as they come from the tree, as they hold their shape better when treated in this way. Canned figs, however, are not common in our markets and their price is high. And yet the factories at Biloxi, Mississippi, and New Orleans at one time put large quantities of canned figs on the market, for the demand was very active up to the panic of 1893, and the canners paid as high as four cents a pound for the fresh fruit and could not get enough to fill orders. Each factory has its own method of canning, and the process usually takes two days. In the finished product the fig holds its shape perfectly but becomes partially transparent, and as the final syrup is clear and free from sediment it is very attractive. All this information is found in a bulletin on Fig Culture just issued by the Division of Pomology of the United States Department of Agriculture, where many interesting facts about the cultivation and curing of figs in California and in the Gulf states are set forth.

The trade in plants for Easter was a very active one this year, and immense quantities of many kinds were sold for home and church decoration. Lilies and Azaleas were, as usual, the favorites, and most abundant, though in the displays made by florists Lilies were not so prominently shown as many other plants which are less popular, and therefore need to be brought to notice. Hydrangeas sold slowly, and one of the most extensive dealers declared that half the Easter stock of these plants remained on the hands of the growers, and the other half which had been sold to the retailers was left on their hands. These plants require more water than they generally receive in households, and so last but a short time and have lost favor. Japan Maples, with bright variegated foliage and trimmed back into small plants, were observed in one collection, and other plants seen in one or other of the best stores were Anthuriums, pink Bouvardias, Kalmias and Otaheite Oranges. The delicately flowered *Spiræa Thunbergii* was noted, but hardy shrubs forced into flower were comparatively rare. Occasional neat little plants of the Australian *Boronia heterophylla* were distinct and bright, with small bell-like carmine flowers. Marguerites were plentiful, as were Ericas, with Lilacs and Cytisus in smaller supply, and but few Cinerarias. There were the usual spring bulbous-flowering plants and attractive pots of Violets, with the cheaper Vincas in flower, and in some of the most costly collections were pots of stockily grown General Grant Geraniums, which, on account of the approaching memorial celebration of the dedication of the Grant monument, were in special demand. Candytuft, Stocks and other herbaceous plants were not unusual, and pots of floriferous Begonias were delicate and pleasing among more bold and conspicuous offerings. One or two of the windows exhibited extravagant arrangements of plants in crêpe paper and broad ribbons, and of large boxes of fanciful colors, and in these same stores some of the plants were veiled in fine silk net. But this attempt at adornment was exceptional, and most of the plants in pots were shown on their own merits, and without any artificial disfigurement. There were some simple and pleasing arrangements of plants in round and oblong baskets, the latter of plainly woven fibre, generally green. Lily-of-the-valley, edged with Violets, and white Hyacinths and Violets, bordered with *Tradescantia*, were two of these simple and natural plantings. A larger basket held tall plants of Lilies, Heather and a few heads of Hyacinths, well grouped and singularly attractive. In another basket nearly a dozen dense and airy heads of *Spiræa compacta* rose in the centre above two colors of Heather and a cluster of several shades of pink Hyacinths, while well-grown Ferns gave a flourishing and established air to the whole.

## The Field of Landscape-art.

WE have already taken occasion to say that the opposition to the recently established forest reservations which is made by members of Congress from certain of the states in which they are situated is not shared by all the people. The *Miner* and the *Electrician*, a paper published in Spokane, Washington, speaks of President Cleveland's act as one of the most statesmanlike measures that ever emanated from the White House. It characterizes the opposition to the reservation principle as extremely shortsighted and selfish, and adds that people of intelligence, whose judgment is not warped by any money considerations in the immediate future, see the wisdom and justice of the act. In fact, it is the people in the neighborhood of the reservations who will receive the most substantial benefit from them, and the future population of the great north-west has rights which the people of this gen-

eration are bound to respect, in spite of the protests of timber sharks and mining promoters who feel that their designs upon the Government domain are in danger of defeat. No doubt, there are many men who honestly think that the proclamation will work hardship to the regions in which the reserves lie, but any one who reads the statement of the commission published in this journal two weeks ago and notes how carefully every privilege of settler, prospector and miner has been considered, must come to the conclusion that no legitimate privilege is imperiled, but that the rights and property of all the people are preserved and guarded against attack by the lawless who think only of their own present benefit.

### *Pinus flexilis.*

THE illustration on page 165 of this issue reproduces a photograph of a remarkably noble specimen of the Rocky Mountain White Pine, *Pinus flexilis*, which is standing in front of the United States military post in the Yellowstone National Park, in Wyoming, where it is growing at an elevation of about 7,000 feet above the level of the sea, and at three feet above the surface of the ground has a trunk diameter of nearly five feet.

*Pinus flexilis* is the first of the Rocky Mountain conifers known to science, having been discovered in 1820 near the base of Pike's Peak, in Colorado, by Dr. Edwin James, the naturalist and surgeon of Long's Expedition to the Rocky Mountains, who described it three years later in his journal of this expedition. It is one of the five-leaved species, although it differs from our eastern White Pine in its usually shorter cones, much thicker cone-scales and nearly wingless seeds, and is more like the Swiss Stone Pine, *Pinus Cembra*, than any other American Pine, differing, however, from that species in the internal structure of the leaves. Never forming very extensive forests, *Pinus flexilis*, which owes its name to the flexibility of its stout and extremely tough branches, is widely distributed from Bow River, in Alberta, southward along the Rocky Mountains to eastern Texas and westward over the mountain ranges of Wyoming, Montana, Colorado, Utah and Nevada to south-eastern California, where it occurs on several of the desert ranges, and even crosses the summit of the Sierra Nevada to the upper waters of King's River, where it grows up to elevations of nearly 12,000 feet above the level of the sea. It is abundant also on many of the mountain ranges of Arizona and New Mexico, and, no doubt, extends over our southern boundary. Most frequently growing singly or in small groves and among other conifers, this Pine is the principal tree on some of the foot-hills of the eastern slope of the Rocky Mountains in Montana, and on many of the ranges of central Nevada between 7,000 and 10,000 feet above the sea-level it forms extensive forests, and is the most valuable tree of the region, giving the name of White Pine to several mountain ranges and districts. In northern Arizona and New Mexico it grows to its largest size, here sometimes producing cones eight or ten inches long, although the cones on this tree growing in Colorado and northward are often not more than three or four inches in length. The Rocky Mountain White Pine is a tree usually forty or fifty feet in height, with a short massive trunk from two to four, or rarely five feet in diameter; occasionally, however, it attains a height of seventy or eighty feet, and at high elevations on the mountains of central Nevada it is frequently reduced to a spreading shrub with stems only two or three feet tall.

Our illustration gives a good idea of the habit of this tree as it grows under favorable conditions, although on the mountains of northern Arizona it frequently produces taller and straighter trunks, which here and in Nevada and Arizona are frequently manufactured into lumber.

*Pinus flexilis* has been in cultivation in this country and in Europe since 1861, when Dr. C. C. Parry collected seeds of this tree and of several other Colorado conifers and sent them to Dr. Asa Gray for distribution. In the eastern states

it has grown miserably. A few of the plants raised from Dr. Parry's seeds, however, have survived, but at the end of thirty-five years are not more than five or six feet high, with feeble branches and scanty foliage. In England it appears to be more successful, and there has recently appeared in *The Garden* a description of a specimen in the Royal Gardens at Kew which produced cones last year. This tree is now twenty-five feet high, with a trunk two feet nine inches in circumference at the base, and two feet in circumference at six feet above the surface of the ground. It is as a curiosity that *Pinus flexilis* will be cultivated in this country and in Europe, and its chief interest and value is in its ability to flourish and produce merchantable timber in such arid regions as New Mexico, Nevada and south-eastern California.

### The Park Systems of Minneapolis and St. Paul, Minnesota.

ABOUT thirty years ago what was then the little town of Minneapolis held a town meeting to consider the purchasing of twenty acres of land for a public park. The opposition to the movement ridiculed the idea that the city would ever extend far over the prairies, and argued that the town itself was then all park.

Fortunately for the still growing city, public spirit prevailed. By 1883 the sentiment in favor of city pleasure-grounds had risen so high that the Council called to its aid a landscape-architect of experience and reputation, Mr. H. W. S. Cleveland, who outlined a scheme for a system of parks, and, above all, of parkways on each side of the Mississippi River, which, if its suggestions could be fully carried out, would give the twin cities of St. Paul and Minneapolis a magnificent and unique system of boulevards and pleasure-grounds.

Upon the lines indicated, with such slight changes as were incident to the rapid development of the city, Minneapolis has worked. And though business depression and other causes have prevented the carrying out of the entire plan, an important beginning has been made by the purchase of land in desirable neighborhoods, and by securing from destruction high banks of the river below the city. St. Paul has not followed this worthy example, and seems disposed to let slip its opportunities and not yet to have awakened to the importance of handsome approaches to its parks, nor even to the crying necessity of buying land to add to them before it becomes too costly.

In 1883 Minneapolis had a population of one hundred thousand souls and a park area of about eighty acres, all told. But the far-seeing policy of Mr. Cleveland was designed to meet the needs of seven times that number of persons. The present park area of Minneapolis, though less than the original scheme provided for, is nearly 1,553 acres, including twenty-three and a half miles of parkways and boulevards. A riverside park has been laid out, and also a strip along the well-wooded eastern bank of the Mississippi has been secured. A fine drive is thus afforded and a park frontage of two miles along the river. It is possible that there may be ultimately a boulevard along its shores to Minnehaha Park, extending south to the military reservation of Fort Snelling; and a recommendation has been made that Lake Amelia be purchased for use as a reservoir to hold the surplus water of the rainy seasons for the use of the Minnehaha Falls during seasons of drought. It is the effort of the Park Commission to secure the west bank of the Mississippi also for the people, and to obtain permission to hold the picturesque region to the south between Minnehaha Park and Fort Snelling, owned by the United States Government.

In addition to the river frontage, Minneapolis has secured on the opposite side of the city a fine chain of lakes, some surrounded and others skirted by parkways. Lake Harriet has an extent of 353 acres, and the Lake of the Isles covers a hundred acres.

Generous donations have been made by public-spirited

citizens, fifty-seven of whom have given land for public use. Of the \$2,250,000 that the Minneapolis parks have cost up to this time, a million has been contributed by citizens, who either gave the land outright, or continue to pay for it in yearly installments of ten per cent. for ten years. The schedule of parks for 1896 enumerates forty-eight different parks and city squares, ranging in size from a fraction of an acre to nearly two hundred acres, and there are plans on foot for a still greater extension of the system. Elaborate reports are yearly published containing photographs which show the charms of the reservations, and it is the aim of the Commission to rival Boston in the extent and beauty of the pleasure-grounds. Playgrounds for the children are not forgotten, and the water frontage affords admirable opportunity for sports of all kinds in summer and winter, boating and skating alternating with each other in making the region of the lakes attractive to the young, while electric cars render the grounds easily accessible.

Though the resources of the city have not been large enough to greatly develop its system, the authorities have wisely expended them in securing land in different parts of the town while it could be bought at a moderate price, trusting to the growing feeling of the importance of parks to enable them to care for the property as it deserves.

The parks of Minneapolis fortunately possess such beauty of lake and river, wildwood and glen, that even in their undeveloped state they are full of attraction. The banks of the Mississippi on both sides for some miles below the city have a height of 150 or 200 feet, and are even precipitous in places. These banks are covered with a magnificent growth of trees and shrubbery. Elms, Oaks, Lindens, Ashes, Buttonwoods, Cottonwoods, Birches, Cherry, Willows and Hornbeam are found there, interspersed with fine specimens of White Pine and an undergrowth of flowering shrubs similar to those of New England. Little rivulets and springs abound, and on the eastern side two or three natural cascades tumble over the rocks, one of which, known as the Bridal Veil, has a peculiar loveliness.

One can take a train or a river steamer from Minneapolis or St. Paul to Minnehaha Park, situated at the junction of the stream of that name with the Father of Waters, and find there a wild sylvan region of one hundred and twenty-five acres in extent, containing the famous silvery waterfall which hurries over the stratified rocks into the glen below, amid a surrounding of picturesque wooded hills, green meadows and running brook, "a New England picture set in a prairie frame." The slender branches of the trees nearly meet above the rushing stream, here and there crossed by a rustic bridge, and the "Laughing Water" dashes into spray over its stony bed after leaping headlong from the cliff. In winter the great ice columns and bowlders heaped high with snow have an impressive aspect, and at all seasons the glen and the waterfall are beautiful. From this park, Minnehaha boulevard, a broad avenue comprising nearly two hundred acres, leads to the chain of lakes which bounds the city on the west. Parks and parkways abounding in trees connect these great sheets of water, and another handsome parkway at the northern end leads back into Minneapolis. Thus the city grounds are provided with easy and desirable approaches from both directions, and electric cars furnish transit for those who cannot drive to them.

The lake parks are visited more frequently than any of the others, and though the improvement of the driveways is still incomplete, the outlooks over the wide, blue expanses, and the noble opportunities afforded for all sorts of water sports, make them very popular and of untold value.

Minneapolis is situated on level ground, but St. Paul is built mostly on the high bluffs of the winding Mississippi, whose valley, from Minneapolis down past Mendota and Snelling, through the city, averages half a mile in width. No better site exists for a grand street than Summit Avenue, and no lovelier views can be found anywhere than those from the Indian Mounds Park and the proposed river

boulevard, but St. Paul does not show such evidences of forethought as distinguish its active rival. Mr. Cleveland's plan suggested beautifying St. Paul as well as its sister city, but the latter seems disposed to allow its unrivaled advantages of situation to slip away from it, and no permanent provision has yet been made for taking care of even its present inadequate system of parks. Since 1894 it has depended on the precarious appropriations made by the Common Council, and barely enough is raised yearly to take care of its existing parks, only one of which is of real importance as to size, Como Park, which contains 396 acres, the remaining portions of its 453 acres being parceled out into twenty-eight small ones.

Money is expended annually on floral monstrosities, such as the Globe, the Elephant, and Gates Ajar, which might far more profitably be employed in permanent improvements. Meanwhile a plan for the acquisition of a tract on the western shore of Lake Phalen to provide a park and boulevard with exceptional water privileges has been before the Board of Public Works for years. This is a desirable area of 129½ acres, and an assessment for its purchase was completely made out last fall, but revoked again in the month of March, 1897; and, moreover, the superb site of the park of Indian Mounds, commanding a wide and varied prospect, and which consists of seventeen acres enclosing the curious tumular antiquities from which it takes its name, has never been enlarged, though the adjacent vacant blocks could now be purchased at a very low rate, much to its advantage.

If these three parks (Como, Phalen and Indian Mounds) could be put on a proper footing and enlarged to the requisite dimensions, the present needs of the city would be reasonably supplied, though it is a pity to lose time before securing the land on the western bank of the Mississippi for future parkways, such as Minneapolis is provided with already.

The approaches to Como Park are unsightly and inconvenient. An avenue eighty feet wide was originally designed to give access to it, but no improvements according to the original plan have been carried out, and the street is disfigured by a street railway running through its centre. The City Council only last year refused to appropriate the small sum necessary to make of this a suitable parkway, with tracks laid in turf on each side. Other plans on foot for public avenues may be some day perfected, but the original magnificent idea of a river boulevard, running seven and a half miles to the Minneapolis line, embracing an uninterrupted panorama of picturesque views along its whole length, has never been carried out, though the land expense would now be very moderate, and the Park Commissioners reiterate their appeals for its purchase.

Lake Como and the Phalen-Gervais group are the extreme southern part of the galaxy of lakes which spangle Ramsey County. Noble scenery studded with other lakes lies due north of these for nine miles, the addition of which to its park system would be greatly to the advantage of the city and its people.

There are 102 acres of water in Como Lake, which has two winding tributary basins in addition to its larger surface. Around this lie over two hundred acres of land with fourteen miles of driveway and twenty-two miles of walks. A heavy natural growth of Oaks shades the region, which is densely wooded in parts, and in others diversified by open lawns, the whole affording a delightful resort. Four hundred and fifty thousand visitors were carried to this park in the summer of 1895 by the electric line alone.

Phalen is a natural park consisting mainly of native forest surrounding 450 acres of water surface, and the plan of improvements contemplates the deepening and widening of a small stream a little over a mile long which connects it with Lake Gervais, so as to make a slack-water channel for boats and motor barges, which would open a nearly four-mile stretch of water promenade through the beautiful scenery of the lakes and intermediate valley. It is a pity that provision for securing the land and for carrying out the

unrivaled system of boulevards and avenues should not be made before the opportunity is lost.

Hingham, Mass.

Mary C. Robbins.

### L'École Nationale d'Horticulture de Versailles.

IN connection with the interesting discussion on Horticultural Education with which several correspondents have been enriching our columns, the following sketch of the great horticultural school of France will, we hope, be considered timely. It was prepared for *The Gardeners' Chronicle* by Jules Gachelin, once a student at Versailles:

The National Horticultural School of Versailles is situated in the grounds of the late "Potager du Roi Louis XIV.," which was established in 1678 by De la Quintinye, inspector-general of the Royal Gardens, in the reign of Louis XIV. Although the grounds and conditions were not very favorable to work upon, he distinguished himself by producing a real "chef d'œuvre" where everything could be grown to perfection. The story says that the king would have asparagus in December, radishes and lettuces in March, strawberries in April, peaches in May, etc., and that he had them, which at that time was a very rare thing.

The glass-houses, where all the fruit, vegetables and flowers were grown, have now been replaced by better ones, but the shape of the garden, with its fine terraces and walls full of beautiful fruit-trees skillfully trained, is the work of this venerable gardener, and there are still a few big Catillac Pear-trees which are supposed to have been planted by his own hands, and which bear every year a heavy crop.

Until the first days of the Third Republic, all the produce of these gardens was used to supply the tables of the sovereigns; and it may be said that Monsieur Thiers, the first president, made use of them up to 1873, when the National Assembly decided that these gardens and buildings should be used as the site of a superior school of horticulture where nothing should be spared to train good professional and practical gardeners.

The school was opened in October, 1874, under the directorship of the late Monsieur Hardy, formerly superintendent of these gardens. The announcement of the opening of the school gave great satisfaction throughout France and abroad, and although the Government gave an annual grant of upward of £4,000 toward the expenses of the school, and £800 a year for scholarships, help was also sent from every part of the Continent and abroad in the form of money, or in contributions of plants of all sorts. Owing to the increasing success of the school every year, the number of students is limited, the average for the last three years being 100 to 110 altogether.

The students to be admitted have to pass an examination in elementary subjects and gardening, the first six on the list receiving a scholarship from the Government of £40, unless they already hold one given by a society or province. Those who hold no scholarship of any sort, but are supported by patrons or can afford it themselves, can enter the school, provided that they have given satisfaction at the examination; any one may be admitted between sixteen and twenty-six years of age. The studies extend over three years, and are divided into two sections, theoretical and practical.

The lectures are on French, grammar, mathematics, geometry, book-keeping, surveying, physics, meteorology and chemistry applied to horticulture and agriculture; zoology, entomology and botany (first year, classification of plants, description of flowers, etc.; second year, anatomy of plants, flowers, descriptions of diseases, etc., cultivation of fruits under glass and out-of-doors, vegetables under glass and out, flowering plants in and out, and ornamental trees), freehand and landscape drawing and water-colors. Different rooms are used for these lectures, which are given by professors appointed by the Government. Various collections of insects, animals, flowers and fruits are open to the students, as well as laboratories in which to experiment in physics, chemistry botany, etc. There is also a field for experiments.

The practical section includes five departments; the student has to remain a fortnight in each under skillful head-gardeners. There are (1) fruit-trees; (2) fruit-trees under glass, and forcing-houses where are grown Grapes, Peaches, Strawberries, Figs, Melons, Pineapples, etc.; (3) hot-houses and propagating-houses; (4) outdoor and soft-wooded plants—a botanic garden, where all sorts of medical and economic plants are grown and carefully labeled; (5) the kitchen garden, where are grown vegetables, forced and outdoor. At the end of every fortnight each student has to report upon his work. In the summer there are frequent excursions made to the chief nurseries or principal places, where the students see the best ways of culti-

vating various plants; and they also attend the horticultural conferences, which are given occasionally, and the shows.

There are two examinations every year; one at Easter to show the student what tasks he has to work at, and one in July to class them for the year; besides these, the professors question the students at intervals throughout the year. Each student has to obtain a certain number of marks to be able to pass through the second year's course; those who do not attain them are declared unable to continue their studies, and leave the school. At the end of the three years they pass a general examination in every branch, theoretical as well as practical, and if they give satisfaction, a certificate is awarded them, and the first two obtain a scholarship from the Government, enabling them to pursue their studies abroad.

Every year the director receives from all parts of the Continent and abroad applications for men to serve as directors of botanic gardens and town gardens, for head-gardeners, superintendents of colonial gardens, professors in schools and horticultural societies; and I may say that some of the most important positions in France and in the colonies are filled by ex-students of Versailles, not to mention those abroad. From Hungary, Roumania, Spain, Portugal and Germany, every year a good many persons come for the same purpose as do the others, to improve themselves at the school; and English, Belgians, Turks, Russians, Japanese, Swiss, Italians, Spaniards and others are found among the students; and they return benefited by the experience gained in the National Horticultural School of France.

In conclusion, I may mention that there is an association formed by the students, which publishes a yearly bulletin which keeps a record of the position of the members, and includes articles on various subjects of interest, including the experiments made at the school during the year.

### London Letter.

SPRING GARDENING IN LONDON.—The tendency of garden art in England now is more in the direction of the natural style than ever. The crusade against summer bedding arose not so much from a dislike for the plants used as from an objection to their misuse in the production of gaudy formal patches of color. We have summer bedding still, but the plants are grouped more after nature's plan, and if a bed of scarlet Geranium or purple Heliotrope is employed it occurs in a position where the effect is good and artistic. The form of the bed is often the cause of its failure to please. If we could do away with the circular, kidney-shaped, crescent-shaped or rectangular bed, and substitute an irregular piece of broken ground, to be ultimately covered by leaf and flower, our gardens would be greatly improved. In any case the geometrical star, or crescent, or monogram form is generally offensive. The prevailing practice among the best gardeners here is to use masses in beds generally round, but with its outline broken as much as convenient by the irregular growth of the plants in it. Only one kind of plant is used for each bed, unless a second one be employed for a double purpose, as, for instance, Pansies under Roses, or Lilies with Rhododendrons. The multicolored bed of Geranium, Heliotrope, Coleus and Lobelia, so popular twenty years ago, was only an exaggerated form of what is bad taste in color mixing.

What is true of summer bedding applies with equal force to the case of spring gardening—that is, to the use of hardy early-flowering bulbous plants for floral display out-of-doors. One has only to compare the beds in the terrace garden filled with regularly placed Hyacinths, Tulips and Daffodils with the effect produced by the same plants when planted broadcast, as it were, in bank or glade, or by the water-side. Sir Watkin, Emperor, Empress and Poet's Narcissi are attractive anywhere, whether in bed or flower-pot, but their grace and charm are nowhere so evident as in the grass glade or slope, or in irregular groups on the lawn. A bed filled with Crocuses is pleasing until one has seen a grass slope studded with them. Tulips and Hyacinths are also much more effective when grouped "any how" on the grass slope or in the wild garden than when trussed on the regulation coffee-colored flower-bed. The present

spring has seen an enormous development of bulb gardening in the parks and public gardens of London, and in almost every case the difference between the wild garden and the formal bedding styles is displayed by a liberal use of both. In some cases the attempts at the more artistic

art is needed for the production of a pleasing wild garden, so called, than is commonly supposed. To so arrange tree and shrub and herb and grass as to produce a pleasing natural effect requires knowledge and taste of no mean order. It is quite true that many so-called attempts at

Fig. 19.—*Pinus flexilis* in the Yellowstone National Park, Wyoming.—See page 162.

style is a failure through faulty planting, either by sticking the bulbs into the ground at equal distances apart, or by planting them in positions where they are out of harmony with their surroundings. Such attempts bring the wild-garden style into ridicule. As a matter of fact, much more

natural gardening deserve the sneers of such authorities as Mr. Inigo Thomas, who calls them wildernesses, not gardens.

The plants used here for spring gardening are generally of the commonest and cheapest character—Daffodils,

Hyacinths, Tulips, Crocuses, Snowdrops, Chionodoxas, Anemones (blanda, apennina, hortensis, nemorosa), Cyclamens, Winter Aconite, Christmas Roses and other Hellebores, Primroses, Cowslips and Polyanthus. If we could obtain Irises of the reticulata section, the big Saxifragas, Adonis, Leucojum and Erythroniums in sufficient quantities they would serve equally well. Emphasis must be placed on the recommendation to employ all these plants with taste. Thus, Cowslips dotted over a grassy slope or lawn would be in good taste, but Polyanthus in such a position would not be. Chionodoxas in the grass do not look at home, and, in fact, will not thrive there, but scattered among the stones and roots of the rock-garden or on large borders they have a charming effect. The idea is, however, the main thing. Once perceive that all such plants as those named are better suited for what we term wild-gardening than for the formal flower-bed, and ways and means will readily suggest themselves.

Mr. Burbidge stated in his paper on bulb culture that Daffodils and Tulips could be grown as easily as Potatoes, given the requisite technical knowledge and suitable soil and climate; the same applies to the cultivation and increase of all the plants here recommended for spring gardening. They must be abundant and cheap before they can come to be used in large quantities, but given the demand and the supply will certainly come. It is not many years since Emperor and Empress Daffodils were worth pounds a dozen; now as many pounds will buy a thousand. Chionodoxa and Galanthus Elwesii used to be doled out in small packets to be grown with care in the flower-pot; now one can buy them at so much per bushel. Still, even now we cannot get enough of them. When people see the effect such plants produce at Kew and in other gardens when used in quantity they have the desire to reproduce this effect in their own gardens. I believe there is a great future for all easily grown plants which flower freely and are effective in the open air in spring. Horticultural taste, in England at any rate, leans in that direction.

London.

## Cultural Department.

### The Hippeastrums.—I.

#### SPECIES AND VARIETIES.

I BEGAN to cultivate Hippeastrums in 1881, and since that time I have added new material from year to year. Although the hybrids are much more striking than the species, I have collected as many of the latter as I could get from dealers and from collectors in tropical America. In many cases I did not succeed in obtaining the true species from their native home. I obtained many species from southern Brazil, British Guiana, Venezuela, Central America and the Lesser Antilles. From the mountains of the Andes, particularly in Peru and Ecuador, where some of the most beautiful species grow, I have as yet been unable to procure material.

All these plants are known popularly as Amaryllis, while in science they are called Hippeastrum. The true scientific term Amaryllis belongs to the Belladonna Lilies of south Africa, which have very similar flowers, but different bulbs, leaves and seeds, the latter being few, large and fleshy, while the seeds of the Hippeastrums are many, flat and light, and can be carried away easily by the wind. All the Hippeastrums are strictly American, being found in the tropics from southern Mexico southward to Paraguay and Buenos Ayres. Hippeastrum equestre has been naturalized in southern India and also on several islands of the Indian Ocean, and the true Amaryllis Belladonna (Belladonna Lily) of south Africa has been detected in the island of Jamaica and also on the Andes of Colombia, on the banks of one of the branches of the Rio Cauca, where it was found by Monsieur André, who supposed he had discovered a new species of Hippeastrum. In *The Gardeners' Chronicle* of 1880 it was described and named after its discoverer, *Hippeastrum Andreanum*. Only recently it has been ascertained that this is the true Belladonna Lily escaped from cultivation.

It is a singular fact that all the Amaryllis are called Lilies by persons with no knowledge of botanical science. Thus, Johnson's Amaryllis is known in the south as the Red Lily; Hippe-

astrum equestre as the Barbadoes Lily, etc. But the name of the nymph Amaryllis has been connected with these plants since the days of Linnæus, and is almost as much a part of the modern languages as Lily, Tulip, Hyacinth or Magnolia. The comparatively unpoetical term Hippeastrum, Knight's Star, will probably never find favor with the general public.

The Amaryllis which is most commonly met with in the gardens of the southern states is the easily managed hybrid Hippeastrum Johnsonii, raised by Mr. Johnson, a watchmaker at Lancashire, England, in 1810, from *H. Reginæ* and *H. vittatum*. This was the first species I tried, and I grew it in the open air in Texas, where it soon formed large clumps. Its brilliancy, fine form, delicate fragrance and luxuriant growth led me to other species and hybrids, among which are the following:

*Hippeastrum vittatum*, from the Andes of Peru. This was introduced into Europe in 1769, and it has become one of the most common as it is among the easiest to grow. Though not of such fine form and brilliancy as most of the hybrids raised from it, it is a beautiful flower. The ground color is white, in the tube greenish, striped, and sometimes veined with crimson. The scape usually bears four delicately fragrant flowers. The common strain of Amaryllis found in most greenhouses originated from this species by crossing it with other species, or in crossing its different hybrids among each other. Far superior to the species is the variety *H. vittatum Harrisonianum*, sent to Europe from Brazil by William Harrison, the introducer of *H. aulicum* and many Orchids from the Organ Mountains. The flowers are very large, pure white, with two red stripes. They are of fine form and substance and very fragrant. It was figured in *The Botanical Register* on plate 988. Some botanists regard this as a probable hybrid between *H. vittatum* and *H. solandriiflorum*. My bulb, which was received from B. S. Williams & Son, London, does not grow very luxuriantly, although it flowers regularly in spring.

*Hippeastrum equestre*, the Barbadoes Amaryllis, Barbadoes Lily, or Orange Lily. This is the type on which the genus Hippeastrum has been based by Herbert. This species is found throughout tropical America from Mexico and the West Indies south to Brazil and Chili. I saw it first in April, 1886, in south Florida, where several hundred flowers were standing close together and produced a wonderfully brilliant effect against a background of tall Pampas Grass. The color of the large open flower is a bright orange-red, with a yellowish white star in the tube. Two to four flowers are usually borne on a scape fifteen to twenty inches high. The strap-shaped leaves, of which six to eight are produced by each bulb, are about eighteen inches long, of a glaucous-green color. As the flowers appear when the plant is in full foliage, the effect is indescribably striking. I have seen clumps consisting of fifty bulbs, almost all of which were flowering. In the greenhouse I have had bulbs of this species from Florida, Barbadoes, St. Vincent, Jamaica, Nicaragua, Venezuela, British Guiana, Honduras, southern Brazil, etc. They vary a good deal in size as well as in the brilliancy of their flowers. Those from St. Vincent, belonging to the variety *H. equestre major*, are the most easily grown, the most vigorous and brilliant. *H. equestre Roezli*, gathered by the celebrated collector in the Andes of Bolivia, has a lighter color and smaller flowers. *H. equestre pyrochromum* appears to be entirely different, having much stronger roots, more robust leaves and scarlet flowers with a greenish tinge. This is by far the easiest grown of all the *H. equestre* tribe. There is also a semi-double variety which I received from St. Vincent. *H. equestre* flowers freely for the first year and the leaves grow normally, but when the winter sets in, if it is kept moist, the roots rot and the bulb soon follows, and if kept dry the bulb begins to shrivel and decays in the inside. The few bulbs that may remain sound are only with great pains restored to a healthy condition.

*Hippeastrum Reginæ*, a native of southern Mexico, Central America, the West Indies and south to Peru and Brazil. This is one of the most beautiful of Amaryllises. Introduced into cultivation in 1728, it was called *Lilium Regium* by Dr. James Douglas in honor of Carolina, wife of George II. It is a strong plant, with large, massive, dark green glaucous leaves. In their earlier stages the flowers show a deep purplish brown hue. The strong scapes, of which two are usually produced by each bulb at the same time, are four-flowered and from twenty-six to thirty inches high. The flowers are large and of a very brilliant orange-scarlet color. Each segment has a broad white stripe in the centre extending two-thirds of its length from the base. The tube is greenish. It is easily grown, and flowers better in the window than in the greenhouse, and really most Amaryllis do better with amateurs than with florists. This species has been fruitful in the production of hybrids; the first known cross, *H. Johnsonii*, having been

raised from it. It multiplies rapidly by offsets, which cannot be said of many others. There is also a double form known in cultivation as *H. Albertii*.

*Hippeastrum psittacinum*, the Parrot Amaryllis of southern Brazil. This was introduced to European gardens in 1814. Although not a showy species, it is interesting on account of its peculiar flowers. It has been frequently used in raising hybrids. One of the most robust Amaryllis now in cultivation, the brilliant Empress of India, was raised by Mr. de Graaf, of Leiden, by crossing this species with the hybrid *H. Gravianum*. It is a strong-growing species with stout flower-scapes two to three feet high, each bearing from two to four large flowers of a greenish ground color, beautifully veined, penciled and margined with bright crimson. Although of a robust constitution, it is easily lost in the greenhouse if its requirements are not carefully met. If watered thoroughly only a few times in winter when at rest, or if kept in a moist or damp place, it invariably rots. The variety *H. psittacinum major* has larger flowers than the common form. It produces its flower-scapes before or contemporary with the long strap-shaped leaves. This species, as well as *H. vittatum* and *H. Reginae*, I have obtained true to name and in best flowering condition from Mr. E. H. Krelage, of Haarlem, Holland. I have found that these bulbs which have been thoroughly acclimatized do much better and give more satisfaction than those imported directly from their native country.

All the species so far considered are deciduous—that is, they have a season of rest when the leaves die down, and a season of growth. They must be kept entirely dry during winter and should only be watered when the flower-scape or the leaves have grown a few inches high, and then only cautiously, once in a week being enough until the leaves or the flower-scape are almost fully grown. If the drainage in the pots is perfect, they require much water when in full flower and foliage. As soon as the leaves begin to die down water must be withheld almost entirely.

*Hippeastrum aulicum* is an evergreen species of very robust constitution. It was introduced to cultivation from the Organ Mountains of Brazil in 1819. Mr. Harrison, its discoverer, found it abundantly in the rich vegetable mold on shady mountain-sides. The peduncle grows from eighteen to twenty inches high, bearing an umbel of two flowers of a very rich, deep, velvety crimson, appearing as if covered with gold dust; the centre is green and the form of the flowers not good, compared with our modern race of Amaryllis hybrids. The flowers appear invariably late in the autumn or early in winter. From this magnificent species many fine hybrids of special merit have been raised, among which *H. Ackermanni pulcherrimum*, one of the most glowing, was obtained by crossing it with *H. Johnsonii*. *H. aulicum* is easily grown and flowered if care is taken that the leaves are kept green. Water must, therefore, never be entirely withheld, as the plant is evergreen. A more satisfactory and more easily grown form of this noble species is *H. aulicum robustum* (*H. Tettani*, *H. Rougieri*), which was introduced from the German colony, Blumenau, south Brazil, by Dr. Blumenau in 1848. Under the name of Amaryllis Tettani large quantities were sent to Berlin and Erfurt. The foliage is very robust, being densely speckled with minute purplish spots on the underside. The two flowers are of a deep crimson with a green star. The bulbs multiply rapidly by offsets, unlike those of the type, which are slow in this respect. The variety *H. aulicum platypetalum* has broader segments and a larger green star, and another variety, *H. aulicum stenopetalum*, has narrower segments than the type.

Milwaukee, Wis.

*H. Nehrling.*

#### Notes from Baden-Baden.

AMONG Muscari I beg to mention the variety *Freynianum* of *M. azureum*, which is the best of the three varieties; its spikes are the largest and the flowers are the best in color, a bright turquoise blue. It flowers early enough, being in bloom here from the middle of February to the middle of March. A little later comes another handsome variety, *M. Szovitsianum subcœruleum*, with robust and showy spikes of pale sky-blue. Soon after *M. polyanthum* shows its large deep blue spikes in great abundance, as it flowers more freely than any kind under cultivation, and is also very showy. *M. elegans* is another gem among these spring flowers; its rolled leaves and the uncommonly long narrow spikes beset with comparatively large individual flowers of deep ultramarine distinguish it as a very showy plant.

*Tulipa Kaufmanniana* is among the earliest of its tribe, and its varieties *Aurea* and *Pulcherrima* are, perhaps, the most gaudily colored and largest-flowered Tulips. Both have out-

side segments of intense, slightly glaucous scarlet encircled by a broad orange-yellow rim; inside they are of a very deep brilliant yellow, with a few scarlet streaks and blotches. *T. suaveolens* is another striking species; the large flowers are all over a deep crimson-scarlet. This species seems to be very rare, and the true plant is scarcely met with in the trade.

Baden-Baden.

*Max Leichtlin.*

#### April Irises.

BETWEEN the flowering of the early-blooming Irises and the first of the rhizomatous section, say, usually from late March to late April, there are a few interesting species which are as distinct as they are attractive. These Irises all belong to the Juno group of the botanists. In a general way they are distinguished by having bulbs with a few thick scales, very thick fleshy roots, which are formed before they go to rest and by the exceedingly small standards of their flowers. They have leaves somewhat Leek-like, stem-clasping and distichous. Some of the Juno group flower in the early winter, and are grown under protection in winter, but the main body is in evidence at this season. Owing to their hardiness and distinct habit, so different from other sections of the family, they may be considered very desirable plants for the hardy border in certain positions. They are bulbous plants, natives of Asia and localities where the seasons are somewhat sharply defined into wet and dry periods. Different plants from the same locality will grow under differing conditions, as some of them have a certain adaptability to unaccustomed environments, but in a general way the proper treatment of deciduous bulbous plants, natives of countries having very dry seasons, is to supply them freely with moisture as soon as they start into growth and as long as they continue to make progress, and to withhold water as soon as indications show that growth has stopped, keeping them as warm and as dry as possible during the resting season. It is difficult to imitate the conditions of a dry steppe in an ordinary garden, and it is sometimes perplexing to choose a position in the open where such plants will thrive. Raised borders, with sashes in summer, or even cold frames, are sometimes used, but these are unsightly, and usually the most available place for such plants is at the foot of a wall with a southern exposure. In such a position, however, there is usually a lack of moisture, even early in the spring, while the plants are growing vigorously, and the cultivator must be prepared to supply water when, as is often the case, the March winds dry the soil. In the garden one should use the hose when water is needed, even if the calendar indicates a wet season. Growing bulbs can scarcely be overwatered.

Of this small group of plants, *Iris orchoides* is the most attractive in the borders, both in flower and in the habit of the plant. It produces stems a foot and a half to two feet tall, and as the internodes and flower-stems are longer than those of other species it is more graceful in habit, while the abundant golden-yellow flowers, though individually small, are very effective. In somewhat heavy soil, and a southern exposure, near a wall, *I. orchoides* flowers regularly here, increases by offsets and bears seed. It would probably be well to lift, remove the offsets and replant it at least every second year as there is a tendency of the plants to become too crowded for the best results. The yellow of the flowers of *I. orchoides* is accented by a black blotch on each fall.

Flowering at the same time is a blue-flowered Iris from Bokhara and Turkestan, *I. orchoides*, var. *cœrulea*. Though this has the long internodes and stems of the type it is scarcely as graceful. The flowers are larger than those of the yellow form and are a light slaty-blue shading to white, with a bright orange ridge, on each side of which appear deep blue linings. My experience with this form is slight, and I do not know how reliable it is as a border plant. Two years ago I had from Rev. Mr. Gates, of Mardin, a few bulbs of what seems to have been known as *I. Mesopotamica*, but which is more correctly *I. Assyriaca*, Haussk., under which name it has lately been introduced by Herr Leichtlin. This is now flowering at a height of fifteen inches. The flowers are some three inches across. The flowers were described as a milky white, but the writer must have had in mind the whiteness of city milk, for even at first the flowers have a blue tint which deepens as they age. It may be said that the flowers of these Irises open in succession from the tip downward, and usually one from each node. The nodes and flower-stems of *I. Assyriaca* are shorter than those of *I. orchoides*, and the leaves are wider and less shiny.

The prettiest blue-flowered Juno Iris, however, is *I. Sindaensis*, which is now in bloom. The leaves of this plant are not as smooth as those of the others, and are slightly glaucous. The flower-stems are short and the flowers rather larger and

have wider petals than those of *I. Assyriaca*. They are frilled on the falls and have a very pleasing slaty blue color.

*Iris Caucasica* and its variety major are dwarf kinds of the same section, with few narrow leaves with horny margins. The flowers are of that degenerate yellow euphionously described by the plant dealer as "light lemon-yellow." As it is improbable that any one's color sense can be gratified by such a futile attempt at yellow, I hesitate to commend this species as a garden plant.

*Iris fumosa* is another yellow-flowered Juno which I have not yet seen in flower, though it is in bud in the border. This Syrian species is said to show a smoky hue of yellow which is not promising, as smoky-hued Irises usually are more curious than brilliant. These plants flower at that unhappy season when the weather is never twice alike. The flowers are indifferent to changes of temperature, like most early flowers, but they do suffer severely from the great enemy of us all—the high drying winds—so that if a sheltered spot can be given them it will be appreciated.

### The Red Cedar.

To the Editor of GARDEN AND FOREST:

Sir,—I was very glad to see this tree recommended in your paper for more general planting in our parks and private grounds. It certainly seems strange that a tree of so much beauty should be neglected, especially in these days when our native trees and shrubs are coming so rapidly into favor. I have found it an unusually easy tree to transplant, and have moved many from ten to fifteen feet in height, with but slight loss; they should, however, be very heavily cut back when moved. In fact, I know of no tree that stands the pruning-knife so well; trees that have become badly misshapen from overcrowding can be readily made into fair specimens by the use of the knife.

Although usually we find these trees growing in rough, stony places, they respond quickly to a more generous treatment, and their annual growth is greatly improved when planted in rich soil. I had on my land some large clumps of poor Cedars, crowded together and choked by a growth of White Birches. After removing the greater part of the Birches, I thinned out the Cedars, subjecting the remaining ones to a vigorous pruning. The soil was then enriched as far as possible, and the result is that the Cedars are greatly improved, and in many cases have become good bushy specimens. The effect produced by so radical a treatment was at first undoubtedly discouraging, but after one season the Cedars had shot out beyond their amputated limbs, and the loss of picturesqueness proved to be but a temporary one. On many country places such clumps are common, and I would advise the owners to experiment on a small scale if they are fearful of the treatment being too radical, and judge for themselves.

This power of enduring the pruning-knife or shears makes the Cedar especially valuable for formal gardening, as you mention, but the true place for its use seems to be the one indicated by nature—that is, for covering the tops of rocky knolls and pastures. Almost all our large parks have appropriate places for such trees; in Franklin Park, near Boston, we have a piece of land to which they would seem to be especially well adapted. In fact, many of the hills were partly covered with old Cedars. Unfortunately, as a facing for these rough, picturesque knolls, thousands of Japanese *Retinosporas* have been planted, looking sadly out of place, and mostly in poor condition.

The peculiar bronze color which they assume in winter has always seemed to me to be a very beautiful one, especially when seen in connection with the bluish green of the White Pine, or when an occasional White Birch is allowed to remain to relieve the soberness of their winter hue. There seems to be, moreover, a great variety of color in the different specimens, some of them being so glaucous as to closely resemble the *Retinospora squarrosa*.

Farther south, in Virginia and Florida, they seem to have a looser and more feathery habit, and the tree loses the rigid upright character so common in New England. At Washington there are many fine specimens, especially at Arlington, where the steep bank of the Potomac in front of the house is covered by some splendid trees that greatly enhance the beauty of the view. In Massachusetts, however, good specimens are rare, and only occur when some tree has had the good fortune to grow undisturbed and alone in some rich pasture.

Wellesley Mass.

## Horticultural Education.

To the Editor of GARDEN AND FOREST:

Sir,—I have been much interested in the discussions in your columns respecting the best methods of giving instruction in horticulture. I do not care to comment upon the various articles, nor upon the subject in general at present; but, in order to add an incidental interest to the subject, I wish to make a brief historical excursion. It seems to be true of any subject that we can never be sure of getting back to the very beginnings of it, and it is none the less true of agricultural education; in proof whereof I now append some statements and propositions made by Samuel Hartlib as early as 1651. The source from which I quote is a little book styled, "An Essay for Advancement of Husbandry-Learning: or Propositions for the Erecting a Colledge of Husbandry: and in order thereunto, for the taking in of Pupils or Apprentices. And also Friends or Fellows of the Same Colledge or Society. London, Printed by Henry Hills. 1651." This quaint little book was placed in my hands by Hon. Andrew D. White, who recently bought it in London. The copy contains the book plate of the illustrious Arthur Young. The book is a small affair, numbering altogether only seventeen pages, and four of most entertaining introduction. This introduction is the only part of the writing which bears Hartlib's name, but the whole book and scheme are his. He asserts that it is the "Narrowness of our Spirits" which makes us miserable, and that if we were properly awakened to the advantages which lie about us "we could not be without Lucriferous Employments." Wherefore he proposes a school of husbandry. "Why may we not conclude that in the Science and Trade of Husbandry, which is the Mother of all other Trades and Scientificall Industries, a Collegiall way of Teaching the Art thereof will be of infinite Usefulness."

The things which Hartlib would teach are set down as follows:

(1) Tillage, or setting or sowing of several sorts of Corne or Graine, for the reliefe and sustenance of man and beast. (2.) The breeding of Cattel (in which the breeding of Sheepe may seem particular). (3.) The feeding of Cattel. (4.) The Use of the Dairie. (5.) The planting of Orchards. (6.) The planting of Gardens. (7.) The breeding and feeding of Swine. (8.) The breeding and feeding of the several sorts of tame Poultry. (9.) The planting of Hops. (10) The sowing of Hempt, Flax, or Rape. (11.) The breeding, preserving and taking of wilde Beasts, as Conies, etc. (12.) The breeding, preserving or taking of wilde fowle, particularly of Duckes in and by a Decoy. (13.) The making and managing of Rivers, Moats, Ponds, etc., for the preserving and taking Fish of all sorts for the use and sustenance of man. (14.) The planting of Woad, and all outlandish rare or extraordinary Roots, fruits or plants. (15.) The dreining, fencing, mowing and making of Grasse in Meadows into Hey. (16.) The making of Malt. (17.) And (that now so exceeding necessary endeavour) the planting all sorts of Wood for Timber or fire. . . .

"As these are encouraged and enabled: so is a Nation more or lesse prosperous, or outwardly happy; both these in their distinct natures or uses are most excellent; and are also (at least ought to be) inseparable companions: of which if either precede it is Ingenuity; for that Industry as it is distinct from Ingenuity, can do nothing till the other have contrived what and how."

The means of securing the establishment of the institution are these:

"That whereas it is manifest, that such a Colledge or Society cannot be erected without the building or buying (at least a long lease at an easie rent, if not the inheritance) of some large and convenient House, with some good quantity of Land adjoining and belonging to it; and it is as manifest that such a purchase cannot be made without good Sums of Money.

"It is therefore desired, that all such Well-wishers to their Country's wealth and prosperity; be pleased to contribute such sums to this good and laudable Worke, as in their own Wisdomes and bounties appear necessary, and deliver the same into the hands of Mr. Samuel Hartlib, whose abundant Zeale for the Publique Good, renders him most worthy to be entrusted therewith, till there shall be a competent Stock obtained for the setting forward of this great and good Worke before mentioned: And to subscribe their Names and Sums; that so the whole Society (when erected) and the whole Nation (when in due time they shall have tasted the sweet effects from hence proceeding) may know to whome to render all due thanks through all Ages, as to the bountiful Promoters of; by contributing to a Designe so much conducing to the good of the present and Prosperity of all Ages to come: a Plentiful Reward to every Noble Spirit.

"It is therefore Offered, that whosoever shall disburse and engage any sum, for the encrease of that Stock, and consequently the employment of the Society: shall by an unerring, unaltering rule, receive yearly; while his money remains in the hands of the said Colledge, for every 100. pound, 20. pound, and so for a greater or lesser sum proportionably. And if any particular Person shall desire to have his sum disbursed, to be employed in any one particular single part of this copious Art here before mentioned; he shall have his desire fulfilled: provided that his Stock be sufficient to drive on that way; and that he be contented to forbear his revenue till nature hath produced the returne.

"And whosoever shall thus engage, shall at any time (upon six moneths warning given) call in and again receive his sum formerly disbursed.

"And all those that shall thus engage, are desired to enter their Names and Sums, by subscribing and delivering the money into the hands of Mr. Samuel Hartlib. And for Security they shall have; As to Law, the Propounders bond; As to Love, the word of him that desires to prove himselfe a just and honest man, to God and man, (to his utmost power) and to all Engagers a faithful Steward."

Having founded the institution to his satisfaction he would next proceed to secure pupils or apprentices; and these were to be attracted by the following plan:

"If any Person of quality have a Son or Kinsman 15. years old or upwards, with whom he will give (besides well-suiting him with all necessary wearing apparel, and more, to the value of twenty marks; in such other necessities, as the Undertaker shall appoint) 60. l. in ready money at his first Entrance, and bind him Apprentice for seven years; he shall be in that time faithfully instructed in both the Theorick and Practick parts of this (of all others) most Ancient, Noble and honestly gainfull Art, Trade or Mystery. And at the end of that time, he shall receive at one entire payment, to set up withal, 300. pound. And shall for foure years next ensuing the end of the said 7. years, receive at the end of every year 100. pound more; the better to support him till he have taken sufficient root." . . .

"Into this Colledge also any man may enter himselfe as a freeman, or Friend to, and Member of the Society; upon the following conditions.

"(1.) He must pay down at his Entrance 50. pound, as given to the Society for the encouragement of Ingenuity in the practice of Experiments, for the obtaining of yet more perfection in this (almost) infinite Science.

"(2.) He must bring with him some skill, at least Ingenuity; and testifie himselfe to be a Well-willer to the profession and professors of Good-Husbandry; and particularly to the Master and Fellowes of this Society.

"(3.) He must produce at least 250. pound as a Stock to set up for himselfe, to be driven by himselfe, according to the best direction and assistance to be given by the Master and Fellowes of the Colledge.

"(4.) He shall (not swear, but) subscribe himself under hand & seale, a faithful Seeker of the Advancement of the Mystery and Society; and to be aiding and assisting, to the Master and the Fellowes to his power, at all times, and in all cases, (his own interest always preserved), and to consent and submit to all such Orders, as shall be from time to time made, by the agreement of the Master and the Major part of the Fellowes of the said Colledge, for and concerning the same Society, and to stand to their Award in any case of difference: And not directly or indirectly to discover all or any part of the same Art or Mystery to any person whatsoever, upon any pretence whatsoever, without their consent first had and obtained.

"(5.) He must be always in Commons at the Hall of said Society; at the rate of 8. s. per week, or such other rates more or lesse, as the then present state of things shall require. And he is always to pay off all arrears at the end of each moneth at the farthest, without any deductions for absence how long or short soever. But if he keep a Servant (who must also be in Commons when present) he shall be allowed to deduct for his absence. As also he is not to be accomptable to the Stable for his Horse when absent.

"(6.) He shall at his first Entrance, pay for Himselfe 10. pound, for his Servant 5. pound, for his Horse 40. s. for their habitation: besides providing of all necessary furniture; but be ever after free till death or departure.

"(7.) Lastly, he must be a single man; and if he shall at any time marry, he is from thenceforth to be accompted dead to the Society, to all intents and purposes whatsoever; save onely in point of debt or discovery."

These propositions seem to have been made public before the date of the volume before me, for, toward the close of the book, the writer again addresses his reader personally and

complains of the "Backwardnesse of men" to join with him; and he then resolves the objections which have been urged against the scheme into three categories:

"First, the supposed Impossibility of performing (on my part) the thing promised.

"Secondly, the Newnesse of the Invention or Contrivance, which renders it within the list of things Inspected.

"Thirdly, the Non-appearance of any such good Security as is held sufficient to encourage men to joyne with me freely, fully and speedily (that is, seasonably)."

To these he made answer, and seems to be somewhat impatient that the scheme should not at once arise into fulfillment. How blessed was Hartlib that he had no prevision, and could not know the long travail of two centuries which lay between him and the agricultural school!

Who was Samuel Hartlib? He seems to have been the son of a Protestant Polish merchant who had fled to Prussia to escape persecution. Hartlib emigrated to England about 1628, and died there about 1670. He identified himself with the literary and educational life of his time, and also wrote profusely of agriculture and religion. He was the friend of Evelyn, Pepys and Milton, and the latter dedicated to him, with much praise, his treatise upon education. He appears to have been one of the group from which the Royal Society sprung. There is record that he spent much of his income in helping indigent scholars, and he finally became so straitened in circumstances that Parliament granted him a small pension. He seems to have been a most benevolent and honorable character, and to have enjoyed the full confidence of his contemporaries. No less than twenty-two books are known to have been written by him, of which the one under consideration seems to have attracted nearly or quite the least attention. There seems to be no record that his desire to found an agricultural school ever came to tangible results; but it would not be strange if this little essay upon "Husbandry-Learning" should, after all, be the chief means of carrying Hartlib's name and life to future generations.

## Recent Publications.

*Nature in a City Yard.* By Charles M. Skinner. New York: The Century Co. 1897.

That any one who deliberately and avowedly writes about nature should be compared with Thoreau is inevitable. It is not surprising, therefore, that the publishers of this neat little book send out with it a slip in which some critic is reported as saying that one can get a good idea of Mr. Skinner's work by imagining Thoreau transported from his home in the woods to a densely populated city and compelled to substitute a Brooklyn back yard for his beloved Walden Pond. Mr. Skinner himself would smile at this comparison, for he does not pose as a poet or a mystic or a profound philosopher. He writes simply like a man of merry fancy with a keen habit of observing the surface of things. He makes no pretense of being an authority on entomology or botany or horticulture, and yet he says many interesting things about insects and their ways, and about plants and their cultivation. He makes no labored attempt to evolve a moral here and there or establish recondite analogies between the processes of the physical and spiritual universe. His essays, which are not without a delicate humor, ripple along in a stream of refined comment upon ordinary city sights and sounds, with nothing to mar their simplicity and grace except an occasional effort at fine writing. The book is neatly printed and has an attractive cover which will harmonize well with the furniture of a shady piazza on a summer afternoon, and the loiterer who picks it up for a half-hour's recreation will not be disappointed.

## Notes.

Catawba grapes are still seen in some of the fancy-fruit stores and look as fresh as when gathered six months ago. A box holding three pounds sells for fifty cents.

During last week 5,242 barrels of pineapples came from Havana to this port. The entire output from Cuba will amount to from 100,000 to 125,000 barrels this season, about half the usual yearly export.

The New Hampshire Experiment Station finds that the varieties of potato which have received the highest commendation from all sections of that state are White Star, Rural New-Yorker No. 2, American Wonder, Carmen No. 3, Governor Rusk and Sir William.

More than one of the English horticultural papers have spoken this year of the good qualities of the white-flowered form of *Daphne Mezereum*, and a correspondent from Wellesley, Massachusetts, writes that it is strikingly handsome there this spring, having been in full flower a long time, and much more beautiful than the common one with magenta flowers. This plant ought to take high rank among our early-flowering shrubs.

Apples are still plentiful, 16,000 barrels having reached this city last week for the local trade, besides about 2,000 barrels for export. Northern Spy and Ben Davis bring the highest prices, with Baldwin, Roxbury Russet and Golden Russet in fair demand at somewhat lower rates. The receipts in New York city at this time last year amounted to 681,002 barrels, while in the exceptional season now ending 1,330,221 barrels have been sold here.

The third number of *Florilegium Harlemense* contains pictures of the light rose-colored single Hyacinth, Gigantea, a plant of unknown origin which appeared first some sixteen years ago; three single early Tulips, Chrysodora (yellow), Canary Bird (Kanarievogel), the white L'immaculée and the dark purple Wouwerman—all good varieties for forcing or outdoor planting; and the large and somewhat coarse Crown Imperial known as Maxima.

In regard to the complaint that Red Cedars grow slowly, a correspondent writes that some small trees planted at Radnor, near Philadelphia, some seven years ago, have grown in height considerably more than a foot every year, while some larger ones planted near have spread out rapidly into bushy specimens. It is to be noted that these trees were set in rich moist soil near water, and this indicates that the Red Cedar is not at all ungrateful for good treatment.

A series of lectures and field-meetings, for the purpose of supplying popular instruction about trees and shrubs which grow in New England, will be conducted at the Arnold Arboretum during May and June. The instruction will not be technical, and the purpose of Mr. J. G. Jack, who will conduct the lectures, is to indicate easy means of distinguishing the common native trees and shrubs and recognizing the foreign species which have been introduced. Applications and further inquiries should be addressed to Mr. J. G. Jack, Jamaica Plain, Massachusetts.

A correspondent of the April number of the *Orchid Review* writes of a specimen plant of *Dendrobium nobile* at Hollin Hall, near Bradford, England, which is carrying 1,134 fine flowers. Five years ago the plant was in an eight-inch pot, half-starved, and the bulb did not measure more than ten inches in height. It is now in a fourteen-inch basket, measuring three feet in diameter, and the longest bulbs are four feet six inches high. The success of Mr. Moorby, the gardener, is due to top-dressing every year with fresh sphagnum and peat, which keeps the compost fresh and sweet. Another important cultural point is the resting of the plants at the proper time by withholding the water gradually and never allowing them to shrivel.

The cold weather last week injured vegetables in Maryland and Virginia, and the asparagus, pea and bean crops were affected even in North Carolina. As the season for some sorts is waning in Florida, and these same kinds are not yet coming from the more northern Atlantic coast states in sufficient quantities, prices for new vegetables are high. For example, cucumbers, from Florida, sell at the rate of three for twenty-five cents; tomatoes, from the same state, at twenty-five cents a pound, and peas, the main supply from South Carolina and Georgia, with the first pickings from North Carolina, at seventy-five cents a half-peck. Asparagus costs forty to fifty cents a bunch. Even French artichokes cost more now than during winter, and bring thirty cents each. Bunches of a dozen or fifteen small carrots cost twenty-five cents; other young and tender vegetables are kohlrabi, beets and onions. Choice strawberries from North and South Carolina cost forty cents a box, and lower grades sell for twenty to twenty-five cents.

No lawn is quite as beautiful as one of fine grasses, but we agree with the *Rural New-Yorker* that a lawn of White Clover, pure and simple, is by no means unsightly, as any one can see by examining some of the little plots about the hotels in the

upper part of this city. This Clover will stand drought better than most kinds of Grass, especially than the Rhode Island Bent Grass or Blue Grass, and it can be readily and easily cut by the lawn-mower, but the point made by the *Rural New-Yorker* is that White Clover, being a leguminous plant, will take up the free nitrogen of the air and transfer it to the soil, and thus enrich it constantly in one of the elements of plant-food. It would be an interesting experiment to see how long a White Clover lawn would last if a little phosphoric acid and potash were applied to it every year.

A circular published by the Entomological Division of the Department of Agriculture, and just issued, describes the natural history and habits of the Strawberry weevil, which is very injurious to the staminate varieties of the Strawberry. The pistillate varieties, except such as furnish a considerable quantity of pollen, are not subject to attacks, because it is the pollen of the flower which furnishes the chief food-supply, both of the larvæ and the adults. This explains the preference of the insect for such varieties as Charles Downing, Sharpless, Wilson and the like. Crude carbolic acid, used in the proportion of one part to a hundred parts of water, if sprayed over the plants, is a good repellent. It does not kill the insect, but it makes the plant distasteful so that they will not feed on it. In the same way the Bordeaux mixture has proved somewhat useful by rendering the foliage disagreeable to the insects. It has also the advantage of being a fungicide and will therefore fulfill a double purpose in plants which are in danger of infection by the blight.

In a bulletin on apple-growing in New Jersey, prepared by Director Voorhees, of the Experiment Station of that state, the average value of the crop per acre throughout the state is set down as something like \$50.00, which shows that under ordinary conditions this crop is fairly remunerative. When orchards are managed with care and skill the returns are more satisfactory, and as an illustration of this Professor Voorhees cites the history of an orchard of thirty acres in Chester township, Burlington County. The soil, a sandy loam with a clayey subsoil sloping to the south-west, was carefully prepared before the stocky two-year-old trees were set in the autumn at a distance of thirty-three feet apart each way. The practice has been to seed the ground with Crimson Clover in July or August, to plow this under the next May, and then to cultivate the surface of the ground four or five times before seeding it again. A thousand pounds of an even mixture of ground bone and muriate of potash is applied broadcast every year before the clover seed is sown. The trees are pruned with tops well open to sun and air, and they are sprayed against insects and fungi. Under this treatment they bear annually fine crops of large perfect fruit, which is handled in the best manner, and the average of marketable apples for some years has been 130 barrels to the acre. The total annual expenses for each acre are \$45.00, the gross returns \$142.50, leaving a net return of \$97.50 an acre. The varieties grown are Williams' Early Red, Hagloe, Orange Pippin and Ben Davis.

Last month Sir John Gorst spoke at Girton on the question of education in rural England, and told his hearers that they could not successfully compete in agricultural products with Continental nations, who sent many things to England which ought to be grown at home. Denmark at the beginning of this century was one of the poorest countries in Europe, and to-day it is one of the richest, because Denmark supplies the English people in manufacturing towns, and even in country districts, with butter, eggs and bacon which Englishmen ought to produce themselves. The people of Denmark attribute their prosperity to the education received in the high schools, where every boy and girl is kept until fourteen years of age; besides this, there are winter and evening schools in that country where any one can study until he is thirty. Sir John also pointed out that the children in rural France were kept at school in the same way, and that, in addition to the money expended for general education, France devoted a million dollars a year to special teaching in agriculture and horticulture. Instruction in these arts, he said, was obligatory even in primary schools in the country, and all over France they had higher schools, schools of practice, and itinerant teachers and experimental plots at convenient distances, where demonstrations were given. There are more than 3,300 of these experimental gardens in France. Sir John thought it was a mistake to endeavor to fit country lads for third-class clerkships in the cities instead of fitting them for country pursuits, since the restoration of prosperity in the rural districts depends upon the intelligence of the country population which furnished the workers.

School Gardens and School Grounds.

A FORTNIGHT ago we spoke of a leaflet sent out from the Cornell Experiment Station, which invited each of the school children of the state of New York to plant a little garden of Sweet Peas and China Asters. The circular contained brief instructions about selecting and preparing the ground, planting the seed and caring for the plants, and promised more complete directions to any who should make request for them. All this was done under a law of this state whose purpose is to broaden out the field of the experiment station and give it something of the character of the university extension work which is carried on now in various directions. A correspondent writes to inquire why the obvious plan of having a garden attached to every school has not been suggested instead of encouraging each child to have a garden of its own. In carrying out the plan of "nature study" in the schools it is argued that a school garden would always be ready to furnish material for investigation in botany and horticulture; it could be made of immediate practical benefit in setting forth some of the elementary principles of plant biology, and it would enable young people to see the reasons for many of the processes of horticulture and agriculture. No one would expect that a school garden would make expert cultivators, but with the aid of such an experimental plot many principles might be learned which lie at the foundation of the sciences upon which horticulture and agriculture rest. To show that is not an impracticable suggestion our correspondent points to the example of Europe where there are school gardens by the thousand, where many of the country schools have botanical museums, entomological collections and cabinets of minerals, and some of them beehives, for purposes of investigation. American children are as apt to learn as any in the world, and yet few of them can give the names of the trees and shrubs they find along the road to school, and fewer still know anything about our common insects and their habits, or the birds which are filling the air with melody these spring mornings. All this is perfectly true, but before our children can be taught effectively in this direction we must first teach the teacher. Two or three months ago in an article on agri-

cultural education we cited the instance of a primary school in Belgium which was visited by a representative of the Association of American Colleges and Experiment Stations. When this visit was made, a class of boys and girls about twelve years old were listening to some instructions which were carried on with the help of simple chemical experiments and skillful questions within their comprehension, so as to stimulate their observation and broaden their knowledge. The particular subject of this lesson was milk, and it was reported that as the different members of the class summed up what they had listened to and seen and thought, it was evident that from this time forth their knowledge of milk, its composition and uses, was considerably wider than it would have been if they had never received the lesson. Around the walls of this schoolroom hung pictures of plants and agricultural implements, and adjoining the school was a small garden in which many kinds of plants were growing and in which different methods of cultivation were tried for the instruction of the pupils. The report went on to explain that this teacher was the secretary of the local horticultural society, and in this capacity he was helping in their business the fathers of the children whom he was instructing. No doubt, these children will be more inclined to avail themselves of the most approved methods of scientific agriculture than they would be without this special training, but this is not all. Their minds will be more thoroughly trained for practical use, and they will be stronger and more logical thinkers than they would have been without this instruction. If, therefore, these leaflets sent out by the Cornell Experiment Station lay the foundation for any systematic preparation of common-school teachers for giving practical lessons in the proper method of studying natural objects, they inaugurate one of the most promising ventures that have recently been undertaken in the field of education.

We should not counsel any teacher to wait before establishing a plant garden until he is as thorough a gardener as the Belgium teacher to whom we have alluded. Any one who is apt to teach and who has enough experience to grow common plants with average success can use a garden in connection with this nature study to good advantage. A mere book-man will fail, but a teacher who is competent to lead and direct his pupils in their personal investigations of the mysteries of nature could find abundant material for helpful illustration in a school garden. We have heard it objected that American schoolboys, out of mere wantonness, would destroy any planting of this kind; and it has been offered as a reason why school-grounds are not more generally beautified with trees and shrubs that the pupils would mutilate them. But, on the contrary, there is the strongest evidence to prove that wherever flowers and shrubs are planted on school-grounds, and the children are invited to aid in their cultivation, they soon acquire an affectionate interest in them, and not only refrain from injuring them, but take pride in protecting and developing them. Boys and girls need playgrounds even more than they need gardens, and the first adjunct to a school building ought to be some place where they can play games—a plot that will answer for an outdoor gymnasium. Few school-yards in the country, however, are so contracted that there is no room for vines or herbaceous plants along the walls of the schoolhouse, and in many places it is possible to have a real garden in which the children can take an active interest and feel a responsibility—a garden where they can learn lessons in order as well as in natural science, and acquire a habit of observing closely the beauties of structure and of adaptation in the different forms of vegetable life. This is apart from the ordering of school-grounds with a primary view to their neatness and beauty. A large proportion of the children of the country spend many hours of the day for five days in the week in the schoolhouse or near it, and certainly if they live upon an unclean floor, with stained and battered ceilings and decrepit

furniture, the lesson they receive in taste and morals will not be the same as it would be if they were in a neat and tidy room with simple and cheerful decorations. If the grounds about the schoolhouse are bare and comfortless they would hardly suggest any refinement or elevation in the instruction within, and certainly grassy, shrub-bordered grounds with well-kept trees will have a more civilized look, and if the minds of the young are influenced by external objects, cleanly and beautiful surroundings ought to suggest orderly habits of life and thought. At all events, there is no reason why, in even the poorest neighborhoods, the grounds about schoolhouses should not be beautified by the shrubs and plants which can be obtained from the nearest wood. Where there is a will there is a way, and a dilapidated schoolhouse with an unshaded and repulsive yard means that the community lacks civilization, that it does not possess even the germs of refinement. School gardens, too, are possible wherever there are a cultivated and enterprising teacher and an intelligent community, and the time ought to be near at hand when a garden and window plants will be considered quite as essential articles of school equipment as maps and apparatus for experiments in the sciences.

DR. AUGUSTINE HENRY, of the Chinese Custom Service, in a personal letter from Mengtse, writes the conductor of this journal:

There is here a fair number of northerly forms, as *Fagus*, *Corylus* (one species each); of *Quercus*, perhaps twelve species. Coniferæ are few, two *Pinus*, an *Abies* and *Cryptomeria Japonica*. The flora seems very varied, with many genera. *Clematis* has, perhaps, fifteen to twenty species; *Lespedeza*, *Desmodium*, *Uraria*, many species. Characteristic *Hupei* plants still occur—*Platycarya strobilacea*, *Buddleia*, several species; but only one *Acer*. I have just found an *Altingia*. But I cannot pretend to go into an account of the flora yet. I must have close on a thousand species in the six months' collecting. I wish I had nothing else to do but botanize, then I might hope to rival Delavay's three thousand species from western Yun-nan.

I have not been to any tremendous forest yet, though I was in one which must have been fifteen miles long. My native has just come back from a forest situated between here and Laohey, which he describes as full of immense trees and lots of big game—bear, wild pig, red deer, musk deer and panthers.

It is very curious to note how persistent the Chinese have been in deforesting their country. On the Red River in Tongking we saw much forest, but the moment we entered the Yun-nan part of the river, only grass hills and little shrubberies. Last month in Tongking, close to the Red River, a herd of wild elephants was discovered in the forest, and two were shot by the French officers. And I imagine elephants must have big forests to live in. So the best collecting ground is on the Yun-nan-Tongking frontier. I hope to set off soon on a trip of twenty days or so.

### Second-growth White Pine in Pennsylvania.

FOREST CONDITIONS.—The valley along the Bear Creek, Pennsylvania, attracts attention by its marked tendency to reproduce the White Pine. The region is practically stripped of its forests and presents a familiar picture of desolation. Small and comparatively young groves are seen now and then scattered over the valley. The kinds of trees constituting these groves vary with the elevation of the valley; the lower portions are chiefly stocked with Hemlock and Spruces, and young White Pine and a few hardwoods are only seen on comparatively drier ground. The ridge land is covered with scrubby Oaks and other young hardwoods, among which the second-growth White Pine, Pitch Pine and the Pine seedlings are usually scattered. The comparatively high ground only seems to offer more favorable conditions for the natural renewal of the White Pine. The Pine on such portions rarely occurs in pure growth, and is usually mixed with Maple, Beech, a few Yellow Birch, White Birch, Hemlock and Spruce, scattering White Oak, Red Oak and occasional Black Cherry. The White Pine in such groves is imposing, even when found in comparatively small numbers, for with its greater height and well-

developed crowns it reaches above all the other sorts of trees and forms a canopy under which they find shelter. The soil is usually protected from the direct rays of the sun by the moderately dense undergrowth, consisting chiefly of young and very small Hemlock intermixed with the hardwoods already named, which are also young and small, under three inches in diameter at breast-height and from five to ten feet high. The soil, being well drained by Bear Creek and a number of other small streams, is kept fresh under the mold layer, which is usually thickly covered with leaves and a few Ferns.

ACRE-YIELD.—The process of regeneration of the White Pine may be fairly illustrated by the following acre-measurements procured from sites representing typical conditions of natural reforestation for the valley. One acre was staked off in a grove on a slope facing south-west. The grove was of hardwoods intermixed with White Pines. The undergrowth consisted of 280 small Hemlock, 146 small Beech, 84 small Maples and 12 small Yellow Birch and White Birch. The loamy sand soil was light, loose, deep, dark brown in color, of medium grain, and with pebbles and gravel intermixed. Of the 216 trees on the acre there were:

80 White Pine, from 6 to 23 inches in diameter at breast-height.									
68 Maple, " 14 " 18 " " " " " " " "	14	"	18	"	"	"	"	"	"
22 Beech, " 6 " 24 " " " " " " " "	6	"	24	"	"	"	"	"	"
14 Yellow and White Birch, " 6 " 24 " " " " " " " "	6	"	24	"	"	"	"	"	"
12 White and Red Oak, " 6 " 14 " " " " " " " "	6	"	14	"	"	"	"	"	"
2 Black Cherry, " 10 " 14 " " " " " " " "	10	"	14	"	"	"	"	"	"
18 Hemlock, " 6 " 14 " " " " " " " "	6	"	14	"	"	"	"	"	"

The height of the White Pine averaged from 60 to 80 feet; the height of the hardwoods did not exceed 50 feet. The age of the White Pine ranged from sixty to eighty years. The volume of boles of the White Pine equaled 2,918 cubic feet, which means an average annual accretion of 41 cubic feet to the acre. Making an allowance of fifty per cent. for waste when the timber is ready for the axe, 250 feet, board measure, may be counted upon as the annual increment to the acre.

Another acre was staked off in a grove on a slope facing north-east. The grove was of White Pine, intermixed with hardwoods, with scattering Hemlock and Spruce. The undergrowth consisted of 200 small Hemlock, sixty-six small Beech, twenty-four small Maple and ten small Spruce. Soil, sandy loam of a reddish brown color, fine grain, medium loose, fresh, deep, with two to three inches of mold on top and a surface cover of abundant leaves, Laurel and a few Ferns. Of the 232 trees on the acre there were:

154 White Pine, from 3 to 23½ inches in diameter at breast-height.									
36 Maple, " 6 " 14 " " " " " " " "	6	"	14	"	"	"	"	"	"
18 Beech, " 6 " 14 " " " " " " " "	6	"	14	"	"	"	"	"	"
16 Hemlock, " 6 " 10 " " " " " " " "	6	"	10	"	"	"	"	"	"
8 Spruce, " 3 " 10 " " " " " " " "	3	"	10	"	"	"	"	"	"

In height and age the trees on this acre were exactly comparable to those described above. The volume of boles of White Pine equaled 5,036 cubic feet, which gives an average annual accretion of 72 cubic feet, or 432 feet, board measure, when ready for the axe. It should be noticed that the density of crown cover\* in both groves was very uneven and did not exceed from 0.5 to 0.7.

GROWTH.—The growth of the young White Pine shows irregularities in its progressive development. Side by side may be found internodes differing more than two feet in length. It is not unusual to measure consecutive internodes and find one from three to six inches, and the other from two to three feet long. The same is true when the annual rings are examined on the various cross-sections; rings three to five millimeters in width may be encircled by others with a width of one millimeter or less. The crowns of the Pine, though not lacking in development, show also a wide difference in their relative length with regard to the total height of the trees. In short, every individual Pine

\* The degree of density is expressed in decimals, taking ten to represent a full cover impenetrable to sun rays.

bears evidence of the irregular and extreme conditions in the various periods of its life. It will not be unexpected, then, to find Pine trees of the same age in the valley differing widely in their dimensions. The average dimensions of trees of various ages given below, and based upon the measurements of fifteen trees, may, however, be taken as an indication of the rate of growth of the White Pine in Bear Creek Valley:

Description.	Age.	Diameter (breast-high).	Height of tree.	Height to base of crown.	Bole, cu. ft.	Merchantable timber, b. m.	Remarks.
Young White Pine grove, mixed with mature Spruce, Hemlock and scattering hardwoods.	53	10½	52	19	16	65	{ Nine trees measured, from 47 to 64 years old.
Hardwoods intermixed with White Pine, Pitch Pine, Hemlock and occasional Spruce.	96	24	82	30	118	557	{ Four trees measured, from 92 to 98 years old.
Ridgeland densely covered with young hardwoods, among which White Pine and Pitch Pine are scattered.	126	30	87	27	167	791	{ Two trees measured of 123 and 128 years old.

From this table it is seen that the growth in height is here comparatively slow for the first fifty years, and much slower for the next seventy-five years, while the diameter for those same periods increases very rapidly, especially during the second fifty years. This is exactly what should be expected from Pine growing in half-open or entirely open groves.  
Washington, D. C.

Foreign Correspondence.  
The Royal Horticultural Society.

THE extent, interest and variety of the plants shown at the last fortnightly meeting were such as one expects to see only at a large exhibition. The hall in which the meetings are held is not nearly large enough to accommodate all the plants now sent to these meetings, and the society will be compelled to place some limit on the number of plants sent by each exhibitor or else a larger hall must be found. The latter alternative is most desirable. It would be a pity to place any limit upon the exhibitors, especially as the quality of the exhibits is almost invariably of a high order. Certainly the result of the activity shown by the society during the last few years has been to make these fortnightly meetings both popular and useful. To be able to go to a centre where all the new and interesting plants can be seen growing is a great improvement upon having to get some idea of them from pictures and descriptions in the papers. The importance of these meetings as a help in the promotion of horticultural taste cannot easily be overrated.

Primulas and Auriculas were the special feature of this mid-April meeting, and they were as well represented and admirable as ever. The season has been a little backward for them, still the collections of show, alpine and fancy Auriculas were large and interesting, and it was a positive pleasure to go from group to group noting the charms of green edges, gray edges, white edges; the selfs and golden eyes among the alpinas, many of them with the meal and color laid on with such mathematical accuracy as to look artificial. One must inspect these plants in such company as Mr. James Douglas, Mr. Sanders, the Rev. F. D. Horner and Mr. Turner to fully appreciate and understand their

points. There is no plant enthusiasm like that of the Auricula fancier. New varieties were awarded prizes and certificates, and altogether there was abundant evidence of the vitality of the Auricula cult. Daffodils were in as strong force as Auriculas, prizes being offered to collections, while in the numerous new hybrids and seedlings shown there was evidence here also that Narcissus has become an established favorite in English gardens, although our friends on the Continent see no beauty in these flowers. The Rev. G. H. Engleheart's collection of new seedlings and hybrids was of the greatest interest, several of them being of quite exceptional merit; one, called Red Prince, after the style of Nelsoni, with a large open cup of rich scarlet, and another named Beacon, of similar character, being considered by some competent judges as two of the most beautiful hybrids yet raised. They were awarded first-class certificates, as also was a new hybrid named Snowdrop, raised from N. albicans and N. triandrus. Mr. Engleheart says his work among the Daffodils is a source of the greatest delight, and one might add that such successes as he achieves ought to be a source of considerable profit also; for it has come to pass that fanciers of these plants will pay five, ten or twenty guineas for a single bulb of a new Daffodil. I should say the two new ones named above are each worth considerably more than the last-named sum. True gardening is, of course, done for love; at the same time the commercial side of the work has an importance which even our wealthiest amateurs nowadays do not overlook.

The Orchids were represented by an exceptionally large number of new and rare kinds, as well as specimens showing good cultivation. The most noteworthy, perhaps, was a hybrid raised by Messrs. Veitch & Sons from Lælia Digbyana and Cattleya Trianae, which resembles the hybrid raised some years ago by the same firm from this Lælia and Cattleya Mossiae, but it is darker in color and differs slightly in the form of the segments. It obtained a first-class certificate. Zygopetalum Perrenondi superbum is a larger-flowered and richer-colored variety than the type raised by Messrs. Veitch from Z. Gautieri and Z. intermedium. It was awarded a first-class certificate. Similar distinction was accorded to a very fine variety of Odontoglossum Wilckeanum named Empress-Queen, and shown by Baron Schröder; it has large full flowers, heavily barred and spotted with red-brown on a bright yellow ground. Two other Odontoglossums obtained certificates, as also did a beautiful example of the old but now rarely seen Dendrobium albo-sanguineum. Large groups of Orchids from Messrs. Veitch, Sander, Low, Williams, Sir Trevor Lawrence, Baron Schröder, Mr. Lucas and others were remarkable for the numerous beautifully grown examples they contained. Epidendrum bicornutum, as vigorous and well flowered as could be wished; Dendrobium Brymerianum, with thirty clusters of flowers; Cymbidium Devonianum, with four strong flower-spikes; Cattleya citrina, in great number and well flowered; C. Shroederæ alba, with fourteen beautiful flowers, and Ansellia Africana, with nine large spikes of pale yellow-brown barred flowers. When it is remembered that these plants, which are valuable and delicate, are brought long distances in treacherous weather and exposed to the unfavorable conditions of an ill-constructed hall, and all for love, no prizes of any kind being given, such displays speak much for the generous enthusiasm of the Orchid devotee.

Erythroniums are most useful plants for spring gardening, and some of them are quite worth growing in pots for the conservatory. E. revolutum, with ovate mottled leaves and scapes a foot high, bearing large rose-tinted flowers over two inches across, was awarded a first-class certificate. Ornithogalum lacteum, an old garden plant of last century, but still one of the best of the Cape species, was awarded a certificate under the name of O. grandiflorum. It has strap-shaped leaves a foot long and scapes two feet high, bearing dense racemes of white and yellow flowers,

each about two inches across. A variegated Potato, the leaves heavily and attractively variegated with creamy white, was awarded a certificate; we may therefore now include the Potato among decorative herbaceous plants. In effect it is not unlike a dwarf variegated Elder. Fuchsia Addington, shown by Messrs. H. Cannell & Sons, is a new hybrid between *F. fulgens* and *F. splendens*, with large pendent clusters of bright crimson flowers of distinctly decorative character; it was awarded a certificate.

Hippeastrums were exhibited by several specialists, and some of the new seedlings obtained certificates. Growers of these plants find it preferable to raise stock from seeds rather than depend on the same bulbs year after year, and as they mature seeds freely and, moreover, are easily crossed one with the other, one gets novelty and improvement as well as vigor in the seedlings thus obtained. The predominant influence of *H. aulicum* is a well-marked feature of all the large-flowered seedlings of *Hippeastrum* in cultivation to-day, while *H. equestre* and *H. reticulatum* are very much in evidence among the smaller forms. These plants are now being grown in large numbers in some tropical countries where the conditions are suitable, and the bulbs are sent to England to be sold by auction in the same way as *Lilium Harrisii*, from Bermuda, is. By the way, I notice that an enterprising planter in Natal has discovered that this Lily may be grown as a field crop there, and he has just sent over four thousand bulbs to be sold in London as an experiment. Yellow-spathed *Richardias* are, I am told, being farmed in the same way, so that before long we shall be able to buy tubers of these plants at as cheap a rate as *Tuberoses*. All the so-called new yellow *Richardias* that we have heard of lately are either *R. Elliottiana* or *R. Pentlandii*.

London.

W. Watson.

## New or Little-known Plants.

### *Sambucus leiosperma*.

IN our number of April 7th last a figure and short description were printed of the black-fruited Elder of the Rocky Mountains, *Sambucus melanocarpa*, and on page 175 of this issue appears the figure of the red-fruited Elder of the high Cascade Mountains, which Mr. John B. Leiberger has distinguished from *Sambucus racemosa* and recently described as *Sambucus leiosperma*.\*

It is a stout shrub with spreading branches six or seven feet high, leaves composed of from five to seven nearly glabrous leaflets varying from oblong to lanceolate, acute or acuminate and sharply serrate, oblong, somewhat flattened cymes of yellowish white flowers and scarlet berries in which are from three to five smooth nutlets.

*Sambucus leiosperma* is the red-fruited Elder of the high mountains of Oregon and Washington, extending, according to Mr. Leiberger, northward to Alaska. Whether the character, the smoothness of the nutlets, by which it is proposed to distinguish *Sambucus leiosperma*, will prove constant, we have now no means of judging. The specimens collected near Crater Lake, Oregon, last summer by Mr. Leiberger and Dr. Coville, of the Department of Agriculture, are certainly very distinct, as appears in our figure. The red-fruited Elder, however, on the Oregon and Washington coast region, judging by a single specimen only, has the distinctly pitted nutlets of *Sambucus racemosa*.

## Plant Notes.

**TULIPA GREIGI AUREA.**—All lovers of Tulips are familiar with the species introduced some years ago by Regel and named *Tulipa Greigi*. It is the most handsome and striking of wild Tulips, having light, glaucous spotted leaves, which are very ornamental, and bold flowers with large wavy petals. The form originally introduced was a brilliant salmon-red in color. Although a most desirable plant, *T. Greigi* is not apt to prove more than a transient

visitor in gardens unless cultivated under special conditions, and as, unlike most Tulips, it does not make surplus buds or offsets, we have until lately been dependent on seedlings for increase of stock. These seedlings usually show some variations in color in reds and yellows. Lately, large numbers of the bulbs have been collected in the Sir Darja region of Turkestan, and it is said that practically there are two types, the red one usually known and the yellow form lately introduced as variety *aurea*. The latter differs from the older type only in the color of the flowers, which may be feebly described as a singularly deep, glowing yellow, with red markings on the exterior of the petals and red blotches over black eyes on their bases within. We can think of no flower with a richer color than that of one of these Tulips, which was sent to this office last week by Mr. Gerard.

*Tulipa Greigi* bears every indication of being a vigorous plant, and its failure to become established in gardens is probably only owing to the unnatural conditions under which it is grown. On the steppes in which it occurs no rain falls, it is said, during five months. This indicates, of course, that the bulbs should be kept perfectly dry after flowering, and the simplest plan, evidently, is to lift them as the leaves die down and store them in a hot dry place till late in the year.

## Cultural Department.

### The Hippeastrums.—II.

SPECIES AND VARIETIES—CONTINUED.

**HIPPEASTRUM stylosum**, the salmon-colored *Amaryllis*, from Guiana and the valley of the Amazon, is an interesting species. It bears an umbel of from three to eight flowers of a bright salmon color. Although growing easily in a warm room, it deteriorates rapidly in the moist greenhouse in winter. I received a plant from Mr. Henry Pfister, head gardener of the Executive Mansion, Washington, to whom it had come from the Sandwich Islands under the name of *Amaryllis Honoluluensis*. Lately I have been informed that this species, together with *H. equestre*, is common in the gardens of Honolulu. It needs tropical treatment in summer, but in the greenhouse it must be kept in a dry warm place during the winter.

*Hippeastrum solandriiflorum*, the Long-tubed *Amaryllis*, is another tropical species. It is a native of Venezuela, Guiana, northern Brazil, Colombia, Panama, Costa Rica and the Lesser Antilles. G. F. Appun, in his interesting work, *Unter den Tropen* (vol. i., p. 240), informs us that it is called "*Lirio*" in Venezuela, and that it grows abundantly on the dry southwestern slope of the coast Andes, where it is a great ornament when the rainy season begins. It flourishes in the open, treeless region among the grass. In cultivation its leaves grow to a height of from twenty-six to thirty inches, and the flower-scape is often more than a yard high, crowned with a magnificent umbel of from four to six long-tubed lily-like very fragrant flowers. The color varies very much, some flowers being milky white, others creamy, and still others almost pure white with red veinings and lines; the interior of the tube is green. In congenial soil and in a tropical climate the bulb grows to a large size, often five to six inches in diameter. Of the variety *H. conspicuum* I have received bulbs fifteen and sixteen inches in circumference. Through the kindness of Dr. A. Ernst, of Caracas, I came in possession of bulbs of the variety *Striatum*. The flowers of this form are exceedingly fragrant, and though more brilliant and conspicuous, their long-tubed shape reminds us of the *Lilium longiflorum*. The color of the blossoms is white, veined with dark crimson. The best of all the varieties is, without doubt, *Conspicuum*, which was introduced into cultivation in large quantities by Haage & Schmidt, of Erfurt, about fifteen years ago. A good picture of it appeared in Regel's *Gartenflora* (plates 949 and 956). The very symmetrical flowers, of which six to eight are borne on a strong scape, a meter high, are creamy white with a delicate rosy blush, veined and lined with purplish crimson. It grows vigorously in a warm atmosphere and develops its strong scapes of deliciously scented flowers before the leaves appear. None of these plants are easily kept in good health in the greenhouse. They really need stove temperature all the year round. In winter they must be placed in a warm, dry position in the stove, and should never be watered until the flower-scape has attained a height of three or four inches. In Herbert's time *H. solandriiflorum* was used freely in cross-fertilization, but of late it has been

\* *Proc. Biological Society of Washington*, xi., 40 (1897).

Fig. 20.—*Sambucus leiosperma*.—See page 174.

entirely abandoned in this respect. The *H. ambiguum*, which was sent from Lima, Peru, to the Glasgow Botanic Garden, and described subsequently by Dean Herbert as a new species, has been ascertained to be a cross between this species and *H. vittatum*.

*Hippeastrum reticulatum*, the autumn-flowering *Amaryllis*, I have been unable to obtain. It is said to be indigenous on the shores of Botafoga Bay, near Sao Domingos, Brazil. Its

variety *Striatifolium* is much more abundant and more beautiful than the type. Large specimen plants, consisting of many bulbs, are not rare in collections. The bulbs are small, short-necked, and the leaves, which are of a deep green color, are banded in the centre with a conspicuous creamy white stripe. Although I have had fair success with almost all my *Amaryllis*, this one I cannot induce to grow or flower, no matter how I treat it. In Missouri, where my plants were kept in a

room near the window, it grew without trouble. Nor can I succeed with the robust hybrids raised from it by Mr. B. S. Williams, of London, such as Mrs. Garfield, Mrs. William Lee, George Firth, Comte de Germiny, etc. My bulbs of the first two hybrids deteriorated, and I finally gave them to Mr. Pfister, who succeeded in the course of a few years in developing magnificent show specimens with them. All these plants flower in autumn, the scapes bearing umbels of from four to five flowers, varying from a bright rosy color to deep scarlet, conspicuously netted with a deeper red. These plants are evergreen, and water should, therefore, never be withheld entirely. A writer in the *Gartenflora* recommends that all these species and hybrids should be placed in the stove when making their growth. "In winter, when at rest, they should not be watered at all, except when the leaves begin to shrivel, and they should be kept in a cool house until they begin to push up their young leaves."

*Hippeastrum procerum* (Amaryllis Rayneri), the Blue Amaryllis, Lily of the Empress, Imperial Amaryllis and Amaryllis Imperatrice, a singular Brazilian plant, departs widely from all other species of the genus, the bulb being large, stem-like, ovoid. The neck stands high above the ground, while all the bulbs of the other species are more or less deeply buried in the soil in their native haunts. The leaves, which hang down on the sides of the bulb, are bright green, edged narrowly with yellowish brown. They are two or three feet long. The flowers are blue. The species is found near Petropolis, from whence it was introduced to France, and flowered first in 1863. Mr. Lietze, the well-known botanical collector at Rio Janeiro, writes me that it grows on the mountain-sides in rather dry and sunny openings. My bulbs never flowered, and always perished after I had them a few years in cultivation. In *The Garden* (vol. xlv., p. 350) a fine plate was published, and your London correspondent, Mr. W. Watson, gave the following account: "According to Mr. Baker, as many as twelve flowers are produced in a single umbel, each flower being six inches long, but the Kew plants produced five and seven flowers, respectively. . . . The largest specimen has a stem-like neck two feet long, crowned with ten falcate leaves, and is a striking plant even when not in flower. The plant is evergreen under cultivation. . . . Cultivated in a pot it lives and grows slowly, but does not flower. Planted out in good loam, well drained, in a position where it will get plenty of light all the year round and in an intermediate temperature, it appears to be quite at home. I may add that in the same house and under the same treatment *Buphane disticha* and *Brunsvigia Josephinæ* have flowered."

*Hippeastrum rutilum*, the Fiery Amaryllis, or Orange Lily, is a splendid species, and with its many varieties is one of the most valuable of the entire genus, since it grows easily and flowers profusely. It is a native of southern Brazil, where also the other varieties, varying in color from salmon, saffron, bright yellow and pale pink to a bright scarlet and fiery orange, are found. The typical species is a strong-growing plant with bright crimson flowers with a green keel extending half-way up the segments. The variety *H. rutilum fulgidum* (Amaryllis Brasiliensis), with bright scarlet flowers, is showier. Other beautiful varieties are *H. rutilum equestriforme* and *H. rutilum subbarbatum*, with umbels of brilliant orange-colored flowers, borne on scapes often three feet high. *H. rutilum crocatum* bears smaller saffron-colored flowers, while those of *H. rutilum citrinum* are bright yellow. *H. rutilum acuminatum* (*H. pulverulentum*) is a variety with pale pink flowers. One of the most strikingly colored varieties, *Ignescens*, with bright orange-scarlet flowers, has lately been introduced in large quantities by Mr. William Bull, of London. I still have most of these varieties, and all do very well, especially *Ignescens*. They all grow in southern Brazil in the deep black vegetable soil, and Dean Herbert's collector found *H. pulverulentum* in such soil with a scape three feet high and the leaves as long, and the variety *Equestriforme* was discovered by Mr. Herbert growing unperceived in a mass of parasitic plants, *Cereus* and *Pitcairnea*, which had been torn off from the face of a rock. In the rage for new plants which marks our time, these beautiful Amaryllis have been nearly forgotten, being at present rarely found in cultivation, though they are much more beautiful and valuable than the majority of plants now offered for sale. It is true they do not offer good material for the commercial florist, being slowly increased and flowering only once in the course of a year, but they are capital plants for the private flower cultivator and the amateur. This holds true of all the *Hippeastrum* species and varieties, and especially of the standard hybrids.

*Hippeastrum pardinum*, Spotted Amaryllis. This unique species is of comparatively recent introduction, having been

discovered in the Andes of Peru by Mr. Pearce in 1866, and sent to Messrs. Veitch & Sons, of Chelsea, where it flowered in 1867. It is so beautiful and so unlike anything else in the line of Amaryllis that it created a genuine sensation. The segments are broad, regular, of a creamy white or yellowish-green ground color, densely spotted and flushed with blood-red. The flowers are very short-tubed and the umbel always consists of two flowers. Not being a very strong grower it needs careful treatment. A number of different colored plates of this plant have been published, but the one that appeared in *The Botanical Magazine* (plate 564 and 565) is a correct representation of the wild species as introduced by Mr. Pearce. A fine form, with exceedingly broad segments of a bright greenish-yellow color, freckled with blood-red, was figured on plate 633 of *Flore des Serres*. Many very beautiful hybrids have been raised from this species, but most of them are difficult to grow. The type does not seem to be in cultivation at present; at least, all my specimens differ more or less from the plate in *The Botanical Magazine*. The exact locality where the first bulbs were collected in Peru is not known.

*Hippeastrum Leopoldii*, Leopold's Amaryllis, another noble species, was discovered by Mr. Pearce in the Andes of Peru and flowered by the Messrs. Veitch in 1869. It was correctly figured in plate 475 and 476 of *The Floral Magazine*, and all other illustrations are incorrect. This is really a glorious species, but I doubt whether the typical form is found to-day in cultivation, and, as in the case of *H. pardinum*, we are not acquainted with the locality where Mr. Pearce gathered his bulbs. The plant is of a robust constitution, two scapes being usually produced by one bulb, each carrying an umbel of two flowers. They are very large, widely open, short-tubed, with broad well-formed segments, which are white at the tip, bright red in the middle, with a bifid white keel in the lower half of the red, and a large greenish-white throat. The original bulbs have evidently been lost and their progeny differ in many particulars, though their form is the same. All the bulbs which have flowered with me vary more or less in the red color and lack the bifid white keel in the lower half of the red which makes the type so strikingly beautiful. Collectors in Peru should not overlook these two unique species. Since the introduction of *H. Leopoldii* a new era in Amaryllis hybridization has begun. All the best modern hybrids are of a robust habit and healthy growth, short-tubed, and show very broad segments. The common hybrids of *H. vittatum* which we find mostly in cultivation cannot compare in beauty with the kinds which have been obtained by using *H. Leopoldii* in cross-fertilization. The hybrids coming nearest to this species are John Heal and Hendersonii coccinea, but they are, unfortunately, rather difficult and slow in producing offsets.

Milwaukee, Wis.

H. Nehrling.

### The Hardy Plant Border.

AMONG early spring-flowering alpine plants there is no more interesting genus than that of *Draba*. At this time, in the rock garden, there are several species in bloom, and although the flowers are small, the compact dwarf habit of the plants, which cling so closely to the ground in the pockets made among the rocks, makes them most interesting to lovers of modest plants. They are easily raised from seed sown in spring, and when they are large enough they may be planted out in the nursery for raising or testing hardy herbaceous plants early in May, and by the end of summer they make good-sized plants for transplanting to their permanent places in the rock garden. A good time to transplant them is about the end of August, so as they will be established in their new quarters before severe weather sets in. They grow best in a dry sunny position, and care ought to be taken that they are not planted where water will lodge around them in winter. Although they love a dry sunny place, yet they like a deep moist soil for their roots to penetrate. Last fall, when transplanting from the nursery beds a number of species of this genus, I was interested to know how deep some of their roots pierced the soil. By careful digging I found that they went down twelve and fifteen inches, although sometimes the part of the plant above ground was not more than one inch in height. This shows that they ought not to be planted in shallow pockets in the rock garden, but in places where their roots can get deep down into the earth away from the hot dry soil on the surface of the ground.

*Draba brumæfolia* is a lovely tufted dwarf plant with small linear ciliated acute leaves, and it bears pretty, small yellow flowers which are produced slightly above the foliage. This dwarf plant has been grown here for a number of years and is perfectly hardy. *D. borealis* grows close to the ground and

makes a nice green carpet, and its flower-stems are produced about four inches above the foliage. The color of the flowers is white. *D. stellata* also makes a good green carpet on the ground, but its flower-stems are six inches high, and has fairly good-sized white flowers. Other species in bloom now are *D. rupestris*, *D. hirta*, *D. lactea*, *D. confusa* and *D. arabians*.

Near relatives of the *Drabas* are the *Aubrietias*, which clothe the ground thickly with their evergreen stems, and at this time they have a fine show of blue flowers. In a dry sunny position and partially rich soil they grow freely and are welcome additions to our garden at this season. The *Scurvy-grass*, *Cochlearia angelica*, is a dwarf British plant with white flowers, which are borne freely now. It grows and flowers well in a shady position. It is about six inches high and its stems are clothed with ovate leaves.

*Viola Munbyana* is one of the earliest of the hardy Violets to bloom here. It has flowers nearly as large as those of *V. cornuta* and of a deep purple-blue color. It has proved quite hardy here for two years, growing freely in a shady position and producing flowers in profusion. Another Violet in bloom, with pretty but small light purple flowers, is *V. sylvatica*, var. *Reichenbachiana*. The variety *cucullata* of *V. palmata* and its white form are also in bloom, and when they are grown in masses they are very effective, as their flowers are borne in such lavish profusion.

The first of the Leguminous plants to blossom is *Orobis Vernus*. This excellent, hardy, early-flowering plant, when the frost is out of the ground, grows so quickly that one is always surprised to see it in bloom so soon after it begins to grow. From its black roots rise healthy green leaves, and in a brief time they are almost hidden from view by blossoms of purple and blue. The flowers have red veins, and the keels are tinted with green and then change to blue. The plant is very easy to grow and it is quite happy either in the sun or when slightly shaded, and it enjoys a light rich soil.

In one of the borders some fine tufts of the lovely *Anemone Pulsatilla*, the Pasque flower, are producing their violet sub-erect flowers. The flowers are about the same size as those of *Adonis vernalis*, and are made up of six spreading silky sepals. The plant grows six inches high and its leaves are pinnate, and the segments many-parted. This lovely *Anemone* ought to be more common in gardens. It is quite happy here in a slightly shaded border and in rather stiff loamy soil. Large clumps of *Adonis vernalis* are grown along the front of the herbaceous border, and their big bright blossoms have been enjoyed for several weeks. When the plants are once established it is better not to disturb them too often. If there is occasion to remove them, this should be done with care and as much soil as possible should be taken with the roots.

The large, stately Crown Imperials are in full bloom now, and they are the tallest plants in the border at this time. *Fritillaria Meleagris* is also in bloom, and its drooping, curiously colored flowers are very interesting. Masses of the common Grape Hyacinth and its white variety are conspicuous in the front row, making a bright show of blue and white. They not only thrive in this climate, but they multiply in a sunny position and in a light, sandy soil. *Arabis albidia*, one of the easiest plants to grow, never fails to give an abundant crop of white flowers. The *Erythroniums* are blossoming freely now, a large bed-planting of *E. albidum* being covered with white flowers. *E. grandiflorum*, a rarer plant with yellowish flowers produced singly or two or three flowers in a small raceme, is past its best. Another rare variety now in bloom is *E. dens-canis*, var. *Sibiricum*. It has flowers of a light chocolate color.

Harvard Botanic Garden, Cambridge, Mass.

### Summer Pruning the Raspberry.

IN the spring of 1892 an experiment was started at the Wisconsin Agricultural Experiment Station to determine the effects of summer pruning upon the growth and fruiting of the Raspberry-plant. This experiment was continued through the season of 1895, but as a portion of the plants, in the mean time, were attacked by the disease known as curl-leaf, the results were not regarded as sufficiently conclusive for publication, and the work is to be repeated.

A few points were, however, clearly brought out in this experiment, one of which is the evidence that summer pruning tends to increase the number of canes, both in the Red and Black Raspberry. When the plants in the differently pruned rows were dug out in the spring of 1896 the crowns were noticeably different in the number of stumps whence canes had been cut off in the annual removal of the dead fruiting

branches, and in the thinning out of the young canes to a definite number. The stumps were more numerous in the pruned rows. In one series the canes had been pinched twice each season—that is, the primary shoot was pinched at the height of twelve to eighteen inches, and the lateral shoots that appeared later were pinched about twelve inches from the main stem. In these twice-pinched plants the increase in the number of stumps was marked. In the once-pinched plants the difference was manifest, but to a less degree.

The structure of the stem in the Raspberry and several allied plants is peculiar in the fact that the stems, while living over winter, die back each year after fruiting, nearly or quite to the crown, while new branches grow out each spring from the crown at the base of the stems of the preceding year, or very often from these stems, slightly above their juncture with the crown. In healthy plants the base of the dead cane is sloughed off from the living portion, which heals beneath the juncture. Since the young shoots have the nature of branches, either from the old stem or from the crown at its base, we might expect that pinching the tips of the growing shoots would stimulate the growth of new canes, as we know it stimulates branching of the canes above ground.

Since the number of young canes in cultivated plantations of the Raspberry is usually too large to permit the best development of the fruit, unless they are thinned out, it would seem that the wisdom of summer pruning may be questioned. In our experiment there was no positive evidence that the yield of fruit was increased in any case by summer pruning, while it was very clear that it was decreased by the twice-pinching process mentioned above.

The formation of gall-like excrescences on roots has been ascribed to excessive pruning. In this experiment the pruning appeared to have no direct influence upon the number or the size of the root excrescences, a few of which were found on the roots of certain plants in all of the rows.

### Plum-trees for Ornamental Plantings.

ALMOST any well-grown Plum-tree is ornamental, though those of American species are usually more so than the Japanese Plums, and much more so than the European Plums. I remember to have seen attention called to the desirable qualities of *Prunus Americana* in GARDEN AND FOREST, but *P. angustifolia*, *P. Watsoni*, *P. maritima* and several members of the *Hortulana* group have quite as much to recommend them. *Prunus angustifolia* is a more graceful plant than *P. Americana* and bears foliage of a fresher green, while *P. Watsoni* makes a good showing in thick shrubby borders. A Plum-tree in full blossom is one of the most charming touches in the spring landscape. I was especially struck by the beauty of these trees this spring during a visit to the Plum orchards of the Maryland peninsula. There the white drifts of Plum blossoms interspersed among the pink of the blooming Peach orchards introduce an element of almost dazzling beauty into the rural landscape. Plum-trees there are very commonly planted in farmyards near the dwelling-houses, where they certainly give a better effect than many of the sorry exotics left by the tree agent. Many of the views which one gets in eastern Maryland in Plum-blooming time suggest the paintings of Mr. Alfred Parsons, and give one a real appreciation of the Japanese love for Plum blossoms. The Japanese Plums, by the way, are especially beautiful in blossom, but are not so attractive in habit of growth. [The popular garden tree in Japan is *Prunus Mume*, an Apricot rather than a Plum, and probably not a native of Japan, but of Corea.—ED.]

But while American Plums are all to be rated together as useful for ornamental planting, there are wide differences among the members of any group. This can be quickly marked among cultivated varieties. Of Americanas, Cheney, belonging to the *Nigra* section, is remarkably beautiful at blooming-time. Its blossoms are very large and abundant and have a beautiful rose-pink tinge approaching the characteristic tint of Peach blossoms. Cheney also remains in blossom longer than most varieties. In the *Hortulana* group Sucker State might be noted for special beauty at flowering-time. Moreman and all the varieties of its class, including Wayland, Golden Beauty, Reed, Leptune and Garfield, are not only magnificent in blossom but have a graceful, slender, drooping habit of growth which would mark them out for ornamental planting. Mr. Kerr's Sophie is a tree of the same form and bears an abundance of blossoms, which show a pretty and peculiar pink in the opening buds.

There are varieties of *Prunus Americana* with nicely doubled flowers if one must have something of that sort.

Seedlings of *Prunus angustifolia* and *P. Watsoni* are apt to sprout from the roots. This, of course, is objectionable, but if one selects named varieties for planting, as he should, they may be worked on stocks which do not sprout. Black knot is a drawback to the use of Plum-trees under some circumstances, but in most cases it can be so easily controlled that it ought not to prejudice planters against our beautiful but neglected Plum-trees.

### Work of the Season.

SUMMER bedding plants will claim attention during the next month or six weeks, and the frequent and extreme changes in weather usual at this season call for judgment in setting out tender plants. In the latitude of New York and Philadelphia May 15th is early enough, and farther north this planting out should be delayed until somewhat later.

Among the earliest plants to be put out are young Carnations and Violets for next winter's supply of flowers; these in most instances have been prepared for the change by growing in a cold frame for a few weeks. Carnations and Violets require well-enriched soil and deep cultivation, though for field culture it is probably the safest plan only to use barnyard manure of good quality as a fertilizer. This should be worked into the ground during the previous fall. A plan successfully followed by many large growers is to plant on new ground each season, or, at least, to avoid planting on the same ground two consecutive seasons. Besides the ordinary advantages gained by rotation, the plants are less likely to contract disease from germs which are carried over in the soil and litter.

The hardier bedding plants—for example, *Verbenas*, *Feverfew*, *Phlox Drummondii* and others—are also in the best condition for sturdy growth if kept for some time in a cold frame. They are then in readiness to follow the early spring flowers, as *Narcissi*, *Tulips* and other bulbous flowering plants, *Pansies* and *English Daisies*.

Tender plants, such as *Crotons*, *Acalyphas*, *Sanchezias*, *Coleus*, *Iresines* and *Alternantheras*, can be handled to better advantage in the greenhouse as yet, and in any event should not be planted out until the ground has become quite warm. If checked by a chill it takes some time for these plants to recover. Cannas are also quite sensitive to cold, and make little headway if planted out too early; from May 10th to May 20th is early enough to set these plants in the open ground. Cannas require abundant manuring and watering. The multitude of new varieties of Cannas seems to crowd out some of the old favorites, such as *C. Ehmanii*, a noble species for large beds, and the flowers of which are not only large, but are the nearest approach to pink that we yet have among Cannas. This species is also well adapted for conservatory decoration, and flourishes better when kept growing all the year than when it is dried off during winter.

Old plants of *Bouvardia* which have flowered during the past winter, if planted out in the garden, will give a large quantity of flowers during the summer and prove useful for cutting. Plants of this character are more floriferous than young plants of the present season.

Begonias of the *semperflorens* type are among available bedding stock, and in some localities prove very satisfactory. They require an abundance of water during dry weather, as do all Begonias grown under these conditions. It is desirable to harden off Begonias in a cold frame previous to planting out, and plenty of light will insure a stocky growth.

A group of miscellaneous flowering and foliage plants can be made an attractive feature of the garden, and will also help to relieve the crowded condition of the conservatory. Among plants well suited for such use are the varieties of *Hibiscus sinensis*, *Abutilons* in variety, *Grevillea robusta*, *Phormiums*, *Ficus*, double *Pomegranate*, *Oleanders* and *Aralias*. All of these are admirable, but require a little care in grouping to avoid clashes of coloring.

In making flower-beds it is necessary in our climate to have the surface of the bed level or even depressed slightly in the centre for all moisture-loving plants. It is practically impossible to thoroughly water a bed that is mounded up in the way often practiced by amateur gardeners.

In the greenhouse the work is also likely to crowd at this season. Among the plants apt to need prompt attention are the young *Roses* in preparation for flowering next winter. It does not pay to neglect these and to allow them to become stunted, and they should therefore be shifted from two to three inch, or from three to four inch pots sufficiently early to avoid any check to their growth, for it may be two months before they can be planted out in the house.

Holmesburg, Pa.

W. H. Taplin.

**Xerophyllum.**—This beautiful plant is found in southern New Jersey and southward, and is in full flower early in June. Last year, while botanizing with Mrs. Treat, we suddenly came upon an acre or more of these plants growing stately and tall, with large racemes of crowded showy white flowers. These are borne on a simple and rather stout stem, from two to four feet high, which rises from a thick bulb-like base. The stem is thickly beset at the bottom with very long needle-shaped, rigid, recurving leaves, while above these are shorter leaves which at the top are reduced to bristle-like bracts. The name in Greek means arid leaves. The plant bears transplanting remarkably well. It is established in Mrs. Treat's garden, and flowers as freely as when growing wild.

Vineland, N. J.

M. Abbott.

**Canna, America.**—We have just had this *Canna* in flower, the third in Dammann's list of so-called "Orchid-flowering" Cannas. It has been something of a surprise to us, for in some way we had formed the notion that it was inferior to *Italia* and *Austria*. In our present opinion, however, it ranks above both. The foliage seems to be stronger and tougher, and is of a color much harder to get in Cannas. It is dark bronzy-red, with irregular and inconspicuous dashes of lighter greenish color. The flowering-stem is tall and strong, bearing a large spike of flowers of the form and size of *Italia*. They are, however, of a most rare and striking color, a sort of brilliant apricot-red faintly spotted with darker salmon. The centre is canary-yellow, marked with the apricot-red of the body color, very much after the pattern of *Austria* and *Burbank*, except that in *America* the centre is lighter-colored than the wings. The blossoms are richer in appearance than any of the earlier Orchid-flowering Cannas. They do not appear to be better in substance, though; and this seems likely to prevent the general use of all the *Canna flacida* crosses in outdoor bedding. If it were not for this flabby quality of their blossoms they would soon very largely supersede the French dwarf Cannas for all classes of ornamental work.

## Correspondence.

### The Red Cedar.

To the Editor of GARDEN AND FOREST:

Sir,—I remember well how I admired the spire-topped Red Cedars as they grew on the banks of the Hudson River between Albany and New York very many years ago. I came to Waukegan, Illinois, fifty-three years ago. The bluffs on the Lake shore were nearly covered with these trees and *Arbor Vitæ*, and the former were abundant on the banks of the inland lakes in Lake County. The large trees were cut down for posts by the few settlers as they bought their lands or preempted them. Although these Red Cedars are not of as good form as those on the Hudson, nor as those in Florida, I had hundreds of the young trees gathered and made belts and hedges of them. I set an example to my neighbors and Red Cedars were planted by thousands.

I did not build my dwelling-house in the nursery until 1851, and as it was exposed to the west winds I planted a circular belt of White Pines on the west and north sides, leaving ample room between the house and the belt. I planted an *Arbor Vitæ* hedge running west from the south-west corner of the house, and in 1853 I built a large frost-proof building west of the *Arbor Vitæ* hedge or belt. From the east end of the *Arbor Vitæ* hedge I planted a Red Cedar hedge, curving to the west as it ran southward. I had no trouble with the other belts; they stand there to-day, every tree living and answering the purpose for which they were planted. The Red Cedar hedge was a failure after eight years' growth, although I tried every way to make it a success. My other Red Cedar belts were abject failures, too.

Two nurserymen, each bought a forty-acre lot and carried on the nursery business here. They have both been dead for many years, and on each lot there is a neglected mass of trees taking care of themselves. On both there are the remains of a Red Cedar belt that has stood for over forty years, and here and there a tree remains alone, but not one to the rod has heart-wood enough for a common fence post. The old Red Cedar trees that made such excellent posts must have been very old, as the trees I have planted stood many years before forming heart-wood, and in using a lot of them for poles I found that the White Pine and Silver Maple poles of the same size endured longer than the Red Cedar poles.

Waukegan is as thickly planted with evergreens as any city I ever saw of its size. Thirty-five years ago a large majority

of these evergreens were Red Cedar. Now I cannot think of but one Red Cedar growing as an ornamental tree, and this is about six feet high.

Waukegan, Ills.

Robert Douglas.

### Maple Sugar in Vermont.

To the Editor of GARDEN AND FOREST:

Sir,—Vermont makes considerably more maple sugar and syrup than any other state in the Union. The average sugar crop is about 15,000,000 pounds, besides syrup. The season just closed has been exceptionally favorable, and this, in conjunction with a marked revival of interest in sugar-making, has carried the figures for 1897 much above the average; how much cannot yet be told. Sugar-makers began tapping from March 24th to April 1st, according to locality. A few days of backward weather marked the early part of the season in northern towns, but everywhere a very heavy run was experienced, which lasted ten days or two weeks. The amount of sugar made from each tree seems to have been unusually large. Some sugar men report an average of from three to four pounds, or even more, from large orchards, but the average through the state is not so high.

The quality of the product is improved every year. This is the result of the improvement in methods of manufacture, which have been notable in recent years. This is also evidence of reviving interest among owners of sugar-trees. There are still a good many large sugar orchards in Vermont which are not worked, but their number decreases.

Prices this year have not been entirely satisfactory. The weakness of the market was partly due, perhaps, to the large crop harvested, but there is a general feeling that there was a still greater increase in the sales of adulterated articles, to the prejudice of pure sugar and syrup. Prices for sugar have varied greatly. Some fancy lots sold in retail markets early in the season as high as twenty cents a pound. Prices for large quantities ranged from five to eight cents, the wholesale price keeping pretty close to five cents. The buying price for syrup in Burlington has ranged from fifty to fifty-five cents, with the retail price anywhere from sixty to ninety cents. It is probable that, with the increased output of maple sugar and syrup, there will be more of both used in the state, and it may be hoped that the lower prices will enable people elsewhere, who do not usually have that pleasure, to enjoy for once some pure maple sweets.

University of Vermont.

### Scymnus marginicollis.

To the Editor of GARDEN AND FOREST:

Sir,—Professor J. B. Smith, in his report on the enemies of the San José scale, just issued, describes the introduction of the beetle *Scymnus marginicollis* into New Jersey, but questions whether it will live so far north. It may be worth while to state that it occurs in New Mexico at Santa Fé, in the Transition Zone (collected by myself, determined by Mr. H. F. Wickham), so there is apparently no reason why it should not survive in New Jersey. It also occurs in the Upper Sonoran Zone, having been found by Mr. Wickham at Albuquerque. In Arizona Mr. Wickham found it at Seligman and Williams, the latter place having an altitude of 6,727 feet—only a few hundred feet lower than Santa Fé. In the same report Professor Smith refers to the fact that we do not know the original home of the San José scale. It may suffice now to state that from evidence lately obtained, which I shall set forth fully on another occasion, I am satisfied that it is a Japanese insect.

Mesilla, N. M.

T. D. A. Cockerell.

### Recent Publications.

*Lawns and Gardens.* By N. Jönsson Rose. With Plans and Illustrations by the Author. G. P. Putnam's Sons. New York. 1897.

Mr. Rose is a practical gardener and he has prepared a treatise which will prove of genuine value to the large and increasing number of those who take a personal interest in their home grounds. It does not aim above the intelligence or æsthetic sense of the ordinary American citizen who has never given any thought to planting and to whom some of the profounder principles of garden-art make no convincing appeal. Beyond the field this book covers there lies a region where a more subtle art holds sway—an art whose examples can be analyzed, but an art which never

can be taught. Essays on ideal gardens and the philosophy of garden-art are lost upon the man of average taste who wants something tangible, something which he can understand and appreciate, something which he can take home and apply to the planting of his city lot or the grounds about his suburban residence. Mr. Rose has planned to give instruction on this level and he has carried out his project with consistent interest in a book of four hundred pages and nearly two hundred illustrations, which are invariably helpful, although many of them are lacking in refinement and show no great merit as works of art. After a chapter on the study of natural scenery the instructions begin at the bottom by explaining the use of the instruments used in surveying and leveling. Directions for planning grounds, especially those of moderate size, are given in the form of a few examples which can be easily understood, and the methods of grading and modeling the surface are illustrated. Then follow suggestions as to the grouping and massing of trees and shrubs, with notes on the placing of specimen plants and detached groups, directions for constructing flower-beds and borders, and such details as are ordinarily entrusted to a skilled head-gardener. The last part of the book, like other works of its class, is taken up with a description of the best trees, shrubs, herbaceous plants and climbers for use in various situations in our climate.

Of course, a handbook like this is not meant to take the place of a professional landscape-gardener. Indeed, the sphere of an artist of high creative faculty is entirely outside of the regulation practice here laid down, but, unfortunately, artists of the first rank in landscape-work are rare, and when a so-called landscape-gardener is employed the chances are that his studies will be devoted to the solution of the more obvious questions of detail which are treated in this work. One who recalls the country places with which he is familiar and makes a note of all those which have been treated in anything like a satisfactory manner, will be surprised to note how few they are. Any book, therefore, which gives in a plain way practical directions for treating grounds so as to make them convenient and for producing effects that will be pleasing and not wearisome, ought to be welcome, and we have no doubt that this beautifully printed book will prove helpful to many beginners who propose with some seriousness of purpose to study the garden possibilities which lie about their houses.

### Notes.

A box of Purple Guigne cherries, from Vacaville, said to be the first to leave California this season, reached New York on Monday, consigned to Messrs. Joseph Hahn & Sons.

In a recent number of *The Journal of Commerce*, of this city, it is stated that a law has been enacted in Bolivia granting concessions in the rubber-producing districts to foreigners as well as natives. The trees which yield this material grow wild on immense tracts of government land in eastern Bolivia, and the industry has heretofore been developed in only a small part of this territory. Much of the rubber now in commerce comes from Brazil, where its production and exportation are restricted by law to citizens of that country.

Asparagus is now fully in season and is coming from Maryland, Delaware and New Jersey, besides the southern Atlantic states. The crop of Bermuda onions is said to be short this season, and besides 30,000 crates which arrived here last week only one or two large shipments are yet expected. New onions are now coming from New Orleans by the carload, but these are neither properly cured nor well packed. The season for onions from Egypt will begin in two or three weeks. New Florida potatoes are now quite plentiful. Crookneck squashes have been in market for the past fortnight and sell at the rate of three for twenty-five cents. Tiny young okra sells at \$1.00 a hundred. Small heads of cauliflower grown under glass on Long Island cost forty to fifty cents each. String beans, from Georgia, are succeeding the Florida crop, and peas come from North and South Carolina.

The abundant crop of fruits in this country last year is still indicated in the trade in dried fruits. Sun-dried and evapo-

rated apples are in demand, notwithstanding the continued supply of fresh apples, and last week the available stock of evaporated apples not held back in cold storage in this city was not sufficient to supply the home and export trade, and prices for the grade rated as prime advanced a quarter cent a pound. During the corresponding term last year 139,888 cases of evaporated apples were sold in New York, and in the present season 415,580 cases, or nearly three times the quantity. Dried small fruits are nearly all closed out, excepting raspberries, but California peaches, apricots and prunes still sell readily at fair prices. The exports of all kinds of evaporated and dried fruits from this port since September 1st amount to 654,053 packages.

Strawberries became more plentiful during last week, and besides the last of the crop from South Carolina, crates and refrigerators of this fruit were forwarded by freight and express from North Carolina and Virginia. On Saturday firm, well-ripened berries of good size and flavor sold for twenty-five cents a quart box. In some of the fancy-fruit stores hot-house strawberries are still on sale, and no more perfect and beautiful specimens of this fruit have ever been seen here. Cups which hold a third of a quart sell for \$1.50. Maple sugar is offered in the fancy-fruit stores in two-pound bricks, the darker product here costing twenty-five cents and the more highly clarified, thirty cents. Almeria grapes, carried over in cold storage, and useful in making up fruit-baskets for travelers, sell for fifty cents a pound. The grape-fruit now offered comes from California and costs from ten to twenty-five cents each. Navel oranges, from the same state, sell for sixty cents, and the fancy King of Siam oranges for \$1.50 a dozen.

A law was enacted at the last session of the Massachusetts Legislature authorizing townships to elect wardens who shall have full care and control of the public shade trees of the town. This officer is to supervise the setting out of trees and their removal, if in his judgment it is for the best interest of the public that any should be removed, and he enters and prosecutes complaints for injuries to public shade trees. Under this act, Mr. James Lawrence has been elected tree warden of Groton, and we have received a copy of a handbill which he has ordered to be posted on all schoolhouses and other public places throughout the township. This notice contains the law under which the warden was elected and enumerates his powers and duties; it contains also a summary of the statutes of the state which prohibit the cutting down or injury of trees along the streets or public roads of the town. These laws are good ones, and if they are only enforced as they should be the street trees of the town will be reasonably safe. The example of Groton and its tree warden is to be commended to the other towns of Massachusetts.

In the winter palace at St. Petersburg is the Nicholas Salon, which is decorated with seventy-two Palms, averaging from twenty-five to thirty feet high. These stand in six rows of twelve plants each, and around each plant-tub is constructed a table at which ten persons can be comfortably seated at dinner. The Palms stand so far apart that their spreading tops do not touch, and the outline of each can be seen to advantage. The skill of the court gardener is shown in the fact that these tubs are only thirty inches in diameter, and they cannot be enlarged, owing to the limited size of the table. As the Palms remain in the palace from January until May, they lose seven or eight leaves every year which must be replaced by as many new ones before the following January. To bring about this growth the plants are turned out of the tubs as soon as they are taken from the palace, the roots are severely shortened with an axe, and the ball is re-tubbed in turfy loam, fertilized with bone-meal, and the Palms are then placed on a warm bed in the Palm-house. Here they remain until their new leaves are developed, and at New Year's they are transported to the palace, well packed in thick coverlets as they are carried through a temperature which sometimes falls to forty degrees below zero.

Among low trailing shrubs suitable for the rock garden there is none more beautiful than the alpine *Daphne Cneorum*, which is found on the calcareous soil in the Jura and southern Alps as well as in Hungary and Transylvania. In its home it is often called the Pearl of the Mountains, and its close clusters of delicately scented rose-colored flowers are now at their best. It is an old plant in gardens, and we call attention to it every year, but its beauty cannot be too highly praised. The roots are fine and thread-like, which shows that they like to wander in deep light soil. The plant is evergreen, and it often burns in the winter. It will not endure thick covering, however, but a light sprinkling of straw, which allows a circu-

lation of air, is highly beneficial. In our mention of this plant in spring we never can refrain from associating with it the hardy Candytufts, which are also trailing sub-shrubs. These are perfectly hardy, and when once established they will endure for many years, and, although the new growth may be killed back in winter, they always start early in spring, and at the extremity of each branch they bear a cluster of dazzling white flowers. The two plants, owing to the marked contrast in the color of their flowers, always look well together, and just now they are both unusually full of bloom.

In some notes on Breeding Tomatoes, contained in a recent bulletin issued by the New Hampshire Agricultural College, the point is made that the Tomato plant is quickly susceptible to careful selection, and that in selecting seed the plant, as a whole, has a stronger hereditary influence than the character of the individual fruit—that is, nothing can be gained in earliness, for example, by selecting seeds from the first ripe fruits, regardless of the general character of the plant from which they come. The same rule holds in regard to the production of new varieties by crossing, so that the more uniform and persistent the parent plants the greater is the chance that their characteristics will be transmitted. When once a desirable variety is obtained it can be kept only by constant selection. Varieties, as a rule, have been short-lived, chiefly because no care has been taken in selecting seed. Poor soils and insufficient cultivation tend to cause a variety to revert. Hybridizing between the large varieties and the clustered or currant-fruited kinds usually results in fruit intermediate in size, and crosses between the potato-leaved varieties and the common-leaved varieties usually result in intermediate foliage. As varieties mix readily when grown in the same field, pure seed can only be assured by selecting from isolated varieties. Rotation is a necessity, and plants grown on the same land from year to year, although highly fertilized, will degenerate in time. Haphazard crossing is of little value, and in order to attain any proposed ideal one must be particularly acquainted with the parent sorts and have clearly defined plans of procedure. When the parents are of a very different character the offspring is likely to be weak, while a cross between closely related species or races is likely to be vigorous. One characteristic of great importance in the Tomato has been too general neglect in producing new strains, and that is the keeping quality which varies widely among different varieties. Experiments at the Cornell Station seem to show that the solid varieties may not be the best keepers.

Like many of the preceding bulletins relating to vegetables, which have been issued by the Rhode Island Experiment Station, the one just issued on Celery is an admirable little tract which will give delight to every cultivator of this plant. No known substitute can take the place of Celery among vegetables, and no cooking or other process can make the blanched and tender stalks more delightful than they are when they leave the skilled grower's hands. Celery needs abundant water, rich soil, and, as the experiments at Kingston seem to show conclusively, it needs especially cool soil about the roots. This may be one reason why the old trench system has never been superseded, for under it the roots are shaded, and when they are properly cooled the diseases known as black heart and blight have no terrors. Seaweed, when spread two inches thick about the plants, is found to be an excellent mulch both for the preservation of water and the cooling of the soil. There is an excellent account of varieties, old and new, and Giant Pascal is said to be, like the Marshall Strawberry, too good for market purposes. The first American booklet on Celery-culture seems to have been written by M. Rössle, landlord of the Delavan Hotel, in Albany. It was Peter Henderson who first advocated, between 1850-60, the change from the trench system to the surface-growing plan, and the development of Celery-culture as a branch of industry has been due more to his writings than to those of any other one person. After the simplification of Celery-culture by growing the plants on the surface the next great advance appeared between 1885-90 in the use of boards instead of earth for blanching, a practice which followed close upon the introduction of the self-blanching varieties. The White Plume is a seedling from an American sport which was introduced in 1884. Paris Golden originated in the garden of Monsieur Chemin, near Paris, at about the same time. In what is known as the new culture, Celery-plants are set from eight to twelve inches apart each way in beds, and when skillfully managed under high cultivation very large yields are secured. Three or four times as many plants are grown to the acre as under the ordinary system, but if the beds are neglected even for a few hours great loss is certain.

Agricultural Education in New York.

THE Experiment Station Extension Law, usually called the Nixon Bill, under which the foundation has been laid of what promises to become an established system of agricultural education in the state of New York, was originally enacted in the interest of the grape growers of Chautauqua County. These men four years ago asked Professor Bailey, as the horticulturist of Cornell Experiment Station, to help them in fertilizing and caring for their vineyards. Of course, he could not undertake to supply expensive plant-food for any one section of the state, for, even if he had sufficient funds at command, other sections would make similar application. The station, however, offered to supervise any experiments which the local horticultural society might undertake, and later on Mr. Lodeman went into the district and outlined some experimental work to be carried on. The people became so thoroughly interested in this work that they made application to the Legislature for a small grant of money to be used for prosecuting it in Chautauqua County vineyards. It was evident, however, that this work, if useful at all, ought to be undertaken on a wider scale, and therefore a grant was made applicable to the Fifth Judicial Department of the state, which included sixteen counties in western New York. A sum of \$8,000 was given to the station to be used "in conducting investigations and experiments in horticulture; discovering and remedying diseases of plants, vines and fruit-trees; in ascertaining the best means for fertilizing vineyards, fruit and garden plantations; in disseminating horticultural knowledge, and in preparing and printing for free distribution the results of such investigation, with such other information as may be deemed profitable in promoting the horticultural interests of the state."

This grant, requested by people of the Legislature of the state, was the first instance, so far as we know, where a farming community definitely demanded the means of extending experimental and scientific knowledge in agriculture; and although the promoters of the scheme did not, perhaps, see its ultimate meaning, it marked a long step forward. In the absence of the Director of the Station, Professor Roberts, and of his assistant, Mr. Lodeman, the responsibility of outlining and carrying this new

work rested entirely upon Professor Bailey, who had no precedents to guide him in using the money. The first year's work was mainly preparatory and was spent in the effort to find out what people needed and what they wanted. Many meetings were held and bulletins published, and at the end of the year a definite conception had been formed of what could be accomplished. This was in 1894, and Professor Bailey estimates that the actual travel in western New York, in pursuance of this bill, was something like 20,000 miles. In the winter of 1895 the people requested the Legislature to increase the grant to \$16,000, which was at once acceded to. This year the work was extended, and a special study was made to determine the actual economic status of the farmer and the remedies for his needs. Besides this inquiry, new experimental work was laid out, many meetings were held, short-session horticultural schools were established in various towns and many more bulletins were published.

In January of 1896 the Legislature was again asked for \$16,000, and the appropriation was granted with great unanimity. The marked feature of the enterprise this year was an effort to apply the stimulus of a distinct educational motive to rural communities—that is, to arouse farmers to an appreciation of what had become an evident truth, that education is the real cure of the trouble and distress in our agricultural communities. The work of Professor Bailey and his assistants, together with their bulletins, had proved that the people need teaching more than they need experimenting, and the work was extended to the rural schools. Here was another new departure, and Professor Bailey testifies that of all the work he has ever undertaken nothing has ever inspired him or his assistants with such enthusiasm, and when they visited rural schools and began to interest teachers and pupils in the common objects about them the awakening of their mental activity was an unfeeling surprise. If there is to be any revival, any beginning of new life to agriculture, here is where it must originate. The best work now going on, therefore, is the endeavor to interest teachers of public schools in nature study, and it is gratifying to learn that the leaflets, of which we have heretofore spoken and which are novel of their kind, have been received with the greatest favor throughout the state, and, indeed, everywhere else. This idea of carrying the study of nature directly into rural communities is the most promising development in the field of agriculture since the experiment stations were established. In January of the present year the people again went to the Legislature and a distinctly new bill was passed. Hitherto the money had been granted to a portion of the state and in the interest of horticulture only. Now the demand came for a bill to apply to the entire state and to the whole field of agriculture, and \$25,000 was asked to begin the work. This, too, was plainly a popular movement, and it passed without any opposition. The work now naturally falls into the hands of the Director of the Station, Professor Roberts, who has had a general supervisory direction of it after the first year. While it was limited to the field of horticulture under the original Nixon Bill, forty-nine bulletins were issued, and the farmers of the state seem to be awakened to avail themselves of the power to bring the agricultural college into direct communication with the rural communities. They show their appreciation of the situation by their demands before the Legislature, and the strength and sincerity of their desire is proved by the readiness with which the Legislature accedes to their petitions.

From time to time we have spoken of this movement as its various phases developed. We have given some account of the itinerant or local experiment work of the expository bulletins as distinct from those which record strictly scientific work, of the striking success of the horticultural schools, and especially of the observation lessons which have been uniformly one of the school exercises. In these observation lessons some small object or part of a plant, like leaves or roots, or flowers or seeds, are put into the hands of all the audience, and after a short

time is allowed for examination they are questioned by the instructor until they realize how much there is to be learned by a careful examination of any natural object and how to use their faculties in the way of discovery. We have also spoken of the elementary instruction in rural schools which has been encouraged by the leaflets recently devised, and we may add now that one of the latest plans is a course of reading which has been devised in such a way as to compel the readers to think. About sixteen hundred persons are now reading systematically, although the plan is but a few months old. The station officers specify certain bulletins which are to be read, and then they ask the readers questions upon them, and in this way they are compelled to do some thinking, whether they wish to or not. Subjects within the farmers' comprehension are always selected. The first subject of study was the soil, and two bulletins were prepared, one on its texture and the other on the moisture it contained, and readers were requested to note anything upon which they needed more light or any statement which they wished to challenge, and were invited to send their queries and opinions to the station after they had thought them over carefully. But, not content with this, specific inquiries were addressed to every reader on both of these subjects, and the questions were so searching that no one could reply to them without some active use of his faculties.

Bulletin 122, published last December, the second annual report of this extension work, describes with considerable detail this experiment, for, of course, it is still an experiment. Nevertheless, every advance has been made with such caution and foresight that one cannot help feeling confident that the scheme, taken altogether, has expanded on most efficient lines. The recommendations in the concluding paragraph will commend themselves to every one. The several agencies which we have named should all be under the direction of a single bureau, removed from partisan influence, and associated with the original investigations in agriculture. This bureau ought to have an intimate connection with the Department of Public Instruction, so as to reach teachers, and through them the schools. Teachers in normal schools should be trained by experts in rural subjects. At the conclusion of this bulletin Professor Bailey notes as a matter to be thought of with astonishment how scant and poor has been the teaching hitherto which has had even a remote relation to the tilling of the soil. Many of our rural books do not seem to have been born of any real sympathy with the farmer or any just appreciation of his environment. It is a significant fact that the farmers of this state, as a whole, have proved themselves willing and anxious to be educated. They are difficult to reach, not because they are unwilling to learn, but because they have not been well taught.

WE have received another letter from Dr. Augustine Henry, of the Chinese Customs Service, in which he mentions a remarkable excursion into the basin of the Red River in China. No doubt, Dr. Henry will, at some future time, give a more complete narrative of this tour through an unknown country, and publish the details of his discoveries. This brief account of the journey, however, is so interesting that we present it to our readers:

I have just returned from an exceedingly interesting trip to the country south of the Red River, in a district ruled over by an hereditary chief, who received me with great kindness. I reached the great range separating the Red River basin from the Black River basin, densely wooded with very large trees (average twenty feet in circumference at six feet from the ground), and toward the ridge, where the trees cease, an impenetrable Bamboo jungle, so that the range is only to be crossed at distant points by passes. The range averages 8,000 feet to 10,000 feet high. As this is the dead-point of the year as regards vegetable life, there was not much out in flower, but I found a magnificent *Rhododendron*, a *Magnolia*, two or three *Camellias*, *Stuartia*, *Daphne* (*Indica*?), a shrub with deliciously scented white flowers, an alpine

*Primula*, two or three *Clematis*, an *Evonymus* with remarkably durable and strong wood, occurring on the range. Two or three large *Aralias* (or kindred genus) occur right up to the summit. A very common tree was the *Tetracentron Sinense*, Oliver. This tree is very large, indeed, but the wood is not esteemed. Its fruit-spikes were lying scattered all over the forests, and most of the seed fallen. However, I secured a few seeds, which I enclose in this note. The tree is of interest from its position in the family *Trochodendraceæ*.

I spent two days on the Red River, where a tropical vegetation exists, and I found the Tomato and *Carica papaya* naturalized and growing abundantly. I found some interesting plants there also. The most marked peculiarity is the bizarreness of the fruits. One tree has pods two or three feet long clothed with a dense covering of brown hair, like the tail of an animal. The Tamarind, Raphis, the Banana were all there in the wild state. I forgot to mention that immense evergreen Oaks occur in the mountain forests.

However, the most interesting point of the journey was the aborigines. In the chief's district, say, a region twenty miles square, in addition to Chinese settlers, no less than seven distinct tribes dwell—distinct, that is, in physiognomy—with language mutually unintelligible, never intermarrying and having little or no social intercourse with each other, and possibly existing in this state for centuries. I collected vocabularies of their speeches, and they divide into three groups—Lolo, Meaozte and Shan. The languages are all of the Chinese type, monosyllabic—that is, non-inflectional, with tones—and the peoples are Mongolic; but behind their Mongolian origin is strong evidence of two other stocks: (a) a pigmy and primitive race, and (b) a negro element; characterized by the receding forehead and thick lips and occasional woolly hair. One people has extremely swarthy skins.

I found the Lolos proper in possession of a written character, in daily use, which seems to be an offshoot from very ancient Chinese (A. D. 1).

So you see how interesting, from many points, this region is. Great red deer and large and small bears occur in the forest, as evidenced by their numerous tracks, and many of the trees were marked by the claws of the smaller bear, who builds a kind of nest in the trees to sleep in.

#### John Evans and his Garden.

FEW persons of the present generation know of the existence of a neglected garden ten miles west of Philadelphia, which in the early days rivaled the gardens of John Bartram at Kingsess, and of Humphrey Marshall at Marshallton. Since the reawakened interest in Bartram's garden, it is surprising that the garden of John Evans should so completely be lost sight of. Situated in a beautiful country devoted to farming and summer residences of rich Philadelphians, and about three-quarters of a mile from Wootton, the celebrated demesne of the late George W. Childs in the famous Welsh Tract, it is still a charming place to visit, although its glory has departed.

John Evans was born in Radnor township, Delaware County, February 13th, 1790, and died on the 15th of April, 1862. He was the son of David and Adah Evans. On the paternal side his ancestors were thoroughly Welsh, while on that of his mother they were partly so. His early education was limited, though he received rather more than was usual at that time. There was a mill on the paternal estate, but he preferred going to a larger establishment to learn the business of milling, and after he had learned it thoroughly he was employed as manager of a larger flour mill, then (1812) recently erected near the present city of Troy, New York.

After his return from Troy he resumed the milling business at the homestead mill, and in 1819 married Ann, the daughter of Benjamin Brown, of Radnor, by whom he had six children. He subsequently engaged in the business of sawing lumber for the Philadelphia market.

Up to about the year 1827 or 1828, John Evans had not shown a great preference for any particular branch of science. About this time he received a visit from his kinsman, Alan W. Corson, of Plymouth, Montgomery County, who had with him a copy of Dr. William Darlington's *Florula Cestricea*, then lately published, and he became from that day an ardent botanist. His kinsman, Corson, and he

took frequent excursions together into the woods and fields. Annual or more frequent visits were paid to the old Bartram botanic garden—then in the possession of Colonel Carr—and to other gardens in the vicinity of Philadelphia. He gathered everything interesting and rare to transplant until the supply from this source was exhausted, when he turned his attention to Europe and entered into correspondence with Sir William J. Hooker, director of the garden at Kew, and by forwarding to that learned botanist annually for many years seeds and specimens of American plants, frequently obtained by long journeys and much labor, he received in return new and often rare plants from various parts of the world, scarcely obtainable from any other source by purchase. During part of the period occupied by this correspondence, Dr. Joseph Hooker, the son of Sir William, made a botanical tour to the Himalaya Mountains, in Asia. Seeds from that almost unexplored region, many of them produced by unknown plants, were forwarded to John Evans, who bestowed a great amount of care and labor upon the propagation of plants from these seeds. He also had a correspondent in Germany.

The premises of John Evans afforded no suitable grounds for an extensive garden specially designed for show and ornament, and yet it is doubtful whether another spot of the same extent contained a greater variety of plants of every habit, and every plant was found in the best place for its propagation and growth.\* On the densely wooded hillside along the mill-race, north of the dwelling, were found magnificent Rhododendrons and other mountain plants, natives of the Himalayas, the Rocky Mountains, the Adirondacks, the Catskills and the Alleghanies, growing side by side in shaded seclusion, and moistened by the spray from the adjacent cascade of the mill-pond. Below, upon a flat on the opposite side of Ithan Creek, was an arenaceous alluvial deposit. Here was found the well-known "sand garden" of John Evans, and clustered within it a great number of species from New Jersey and many strangers from similar soil in more remote regions. The arid, rocky hills were covered with Pines and other conifers. The damp, shaded ravine had its Canebrake, the artificial pond its odoriferous Water-lilies and other aquatics, and every border and every corner were occupied by appropriate specimens brought together from remote parts of the earth. A large proportion of the labor required for the care and cultivation of this great collection was performed by the hands of its owner. The sawdust from his mill was used extensively around the growing plants to smother weeds. This soon decayed into a rich mold that promoted the growth of the plant.

The extent of the Evans collection is not accurately known, as no catalogue was ever published. In the number of distinct species of trees and shrubs it was doubtless unrivaled in his day, while in herbaceous plants it had few equals.

The garden at the present day is in a good state of preservation, although many changes have been wrought in the buildings and their surroundings. The mill has been torn down and the house altered to suit the tastes of the present owner. A splendid specimen of *Cephalotaxus Fortunei* stands back of the house along the mill-race, associated with several large Box-trees and Yews. A well-grown *Cryptomeria* also attests to the variety of arborescent species in former days. *Daphne Mezereum* is abundant as an undershrub in some parts of the wooded tract, while the *Periwinkle* (*Vinca*) covers the ground in many places. An interesting variety of the English Ivy growing against a stone wall along the driveway leading up to the house is peculiar in that the terminal leaders have an upright, independent habit with triangular or deltoid leaves, and provided abundantly with fruit. Several *Magnolias* on the lawn are of good size. The *Rhododendron* thicket in the woods back of the house along the mill-race is still in good

preservation, although when a visit was paid to the garden it was too early to judge of the botanical richness of the species. Nothing remains to indicate the location of the "sand garden" except one or two specimens of *Yucca filamentosa*. That the garden was formerly rich in species is proven by the fact that in the herbarium of the University of Pennsylvania many specimens from the garden are preserved, showing the former richness of its flora fostered by the hands of John Evans.

With John Bartram and Humphrey Marshall, John Evans completes a trio of self-taught botanists, all born within the limits of old Chester County, Pennsylvania, and the first within the present county of Delaware, which was partitioned off from the original Chester County. They were men of like tastes and were alike in their industrious and frugal habits. They were all men of the strictest integrity and highest moral worth, and especially were they devoted students of the vegetable kingdom. Each reared his own monument in the large collection of growing plants he left behind him.

University of Pennsylvania.

John W. Harshberger.

### Three West-American Conifers.

SEVERAL so-called marked varieties of our western conifers, I am convinced, are entitled to take rank as species. Crowding two or more marked forms into one polymorphous group, while it emphasizes the fact that they are related, gives us little other knowledge of them. We know in this age of the world that all groups of plants are connected, more or less closely, and we believe that they are all derived from a few simple, primordial forms. As we meet with the termini of these lines of development we find them greatly diversified while also retaining vestiges of kinship. We advance knowledge of these lines—these genera and species—more by detecting and separating than by ignoring and generalizing.

Prevalence of the following forms over large forest areas, combined with many conspicuous differences, both in habitat and structure, demands, in my opinion, this long-delayed recognition.

*PINUS SCOPULORUM*, nom nov.\*—Rocky Mountain Yellow Pine. Small trees, rarely exceeding a hundred feet in height and four in diameter, spire-shaped in outline, the grayish bark thinner and harder, the sapwood thicker and the cones smaller, and with firmer, darker scales than in the typical *P. ponderosa*. Foliage thinner, more inclined to be tufted at the ends of the branchlets, leaves usually in threes, but often in twos.

Sparsely distributed on the high slopes and plateaus of the Rocky Mountains, from British Columbia southward through Montana, Idaho, Wyoming and Colorado to northern New Mexico, and eastward to the Black Hills of North Dakota and Nebraska.

The "polymorphous" *Pinus ponderosa*, with headquarters in the Sierra Nevada of California, and extending along on the western ranges northward through Oregon to Washington, and southward through Arizona to Sonora, probably contains several more forms marked enough to rank as species—notably the "Brown-bark Pine" (my variety *nigricans*)—forming almost exclusively a large forest on the great Colorado plateau of central Arizona and New Mexico.

*PICEA COLUMBIANA*, nom nov.†—Trees usually small and slender, rarely exceeding seventy-five feet in height, with a diameter of three feet. Bark light-colored, thin, hard and flaky; branches short, especially those on the upper half or two-thirds of the trunk, rendering the tree spire-like in out-

\* *Pinus ponderosa*, var. *scopulorum*, Engelm. in Brewer & Watson *Bot. Cal.*, ii., 126 (1836). Sargent in Xth U. S. Census, *Forest Trees of N. A.*, ix., 193. Lemmon in 2d *Bienn. Rep. Cal. State Bd. Forestry*, 98; 1st and 2d eds., *Hand-Book West-American Cone-Bearers*, 7 (1892); also in 3d (Pocket) ed. of same, 34. Coville in *Con. to U. S. Nat. Herb.*, iv., 22.

† *Picea Engelmanni*, Engelm. in part in several publications. Sargent in Xth U. S. Census, *Forest Trees of N. A.*, ix., 205 (1884), in the reference to trees "rare and of small size in the mountains of Montana, Oregon and Washington"; Lemmon in 3d *Bienn. Rep. Cal. State Bd. Forestry*, 113, so far as relates to the north-western form.

\* The garden is best reached at present by alighting from train at Rosemont, Pennsylvania, on the Pennsylvania Railroad, and taking Robert's Road to Ithan Creek; the present owner is William H. Ramsey.

line; annual branchlets slender, two to three millimetres thick, those on the upper branches clothed in the bearing season with small yellowish, narrowly elliptical cones one and a half to two inches long; the scales thin, obovate, obtuse, with scarious, wrinkled edges, the scale-bracts very small, four to six millimetres long, acute; seeds brown, two to three millimetres long, with convex, obovate, shining wings. Forms a portion of the forests on the mountains of Oregon, Washington, Idaho, Montana and British Columbia, extremely northern and alpine forms being reduced to mere shrubs. The true *P. Engelmanni* inhabits the mountains of Wyoming, Colorado, Utah, New Mexico and Arizona, and attains a much larger size, often exceeding 130 feet in height, with a diameter of five feet. Bark thick, brown, deeply furrowed; lower and middle branches long, making the tree fusiform in outline; the branchlets robust, three to five millimetres thick; cones elliptical, two to two and a half inches long, brownish, the scales subrhomboid in outline, thicker and firmer than the other species, the scale-bracts four to six millimetres long, truncate or spatulate; seeds and wings comparatively large.

*ABIES SHASTENSIS*, nom. nov.\*—This, the Shasta Red Fir, often attains a medium size, 100 to 120 feet in height, with a diameter of three to four feet. Bark dark outside, red within, deeply furrowed; foliage less robust than that of the typical *Abies magnifica*; the cones usually elliptical, with more protuberant scales, the apophyses clothed with short, stiff, recurved, brownish hairs; the scale-bracts usually developed to a great length, extending one-half to one inch from between the scales. Headquarters around the base of Mount Shasta, California, at altitudes of 5,000 to 8,000 feet, forming a large, dense, almost exclusive Fir forest. A few trees are found on neighboring slopes of the Scott, Trinity, Siskiyou and the southern end of the Cascade Mountains in Oregon. The true *A. magnifica*, reported originally from "the high unexplored part of the Sierra Nevada to the eastward of San Francisco," attains a much larger size, often 250 to 300 feet high, with a diameter of eight to twelve feet, its magnificent columnar trunk naked to a height of 100 feet; bark light brown outside, madder-red within, deeply fissured, on the largest trees three to five inches thick; the large purple or yellowish cones are almost cylindrical, truncate; the scale-bracts undeveloped, usually completely concealed. This, the Magnificent, or California Red Fir, inhabits the high Sierra nearly from end to end, usually mingling with other trees, rarely, as in the central portions of the Sierra, it forms almost exclusive forests of exceeding grandeur.

Oakland, Calif.

J. G. Lemmon.

## New or Little-known Plants.

### *Ribes erythrocarpum*.

THIS pretty *Ribes* was discovered by Dr. F. V. Coville, of the Department of Agriculture, who found it last August in flower in the neighborhood of Crater Lake, in southern Oregon, then a virgin territory for the botanist. At an elevation of about seven thousand feet above the sea, it is comparatively common in the shade of noble trees of *Tsuga Pattonii*, which here grows to its largest size and forms the principal part of the forest. It was found a month later with ripe fruit in the same locality by members of the Forest Commission of the National Academy of Sciences.

*Ribes erythrocarpum*† (see illustration on page 185 of this issue) is a trailing, glandular hirsute shrub with elongated,

slender, unarmed stems rooting and producing short ascending branches five or six inches in height, rugose orbicular, three to five lobed, coarsely crenate leaves, erect racemes of from ten to twenty flowers with glandular calyx-lobes and broadly spatulate reddish petals and erect subpyriform to spherical bright scarlet fruit about half an inch in diameter and covered with glandular hairs.

In the structure of its flowers *Ribes erythrocarpum* is closely related to *Ribes laxiflorum*, from which it is distinguished by its prostrate stems, and glandular hairs which resemble those of *Ribes viscosissimum*.

The seeds of this *Ribes* have been sown in the Arnold Arboretum, and it will probably, therefore, be possible to test the value of this pretty and distinct species as a garden plant.

## Plant Notes.

### Pelargoniums at Cornell University.

THE issue of GARDEN AND FOREST for July 25th, 1894 stated that a prize offered the year previous by the Massachusetts Horticultural Society for Pelargoniums did not bring out a single entry. It will be no surprise, then, to learn that of the more than 400 varieties of this beautiful flower now in bloom in the forcing-houses of the horticultural department at Cornell University, very few were obtained from eastern growers. The plants of the Zonal-inquinans races (popularly, Zonal Geraniums, Fish Geraniums, Horseshoe Geraniums, etc.) and the Ivy-leaved Geraniums were almost all furnished by E. G. Hill & Co., of Richmond, Indiana, and W. P. Simmons & Co., of Geneva, Ohio, and the Show and Fancy Pelargoniums from John H. Sievers, of San Francisco, while Geranium fanciers here and there have added to the collection. Botanically, these are all Pelargoniums, but the old name Geranium has clung so persistently to three of the races, namely, the Zonal, the Ivy-leaved and the Rose or Sweet-scented, that until the true botanical name shall have come into general use, one runs less risk of being misunderstood by following the gardeners' nomenclature. Of the varieties at Cornell, more than 300 are Zonal Geraniums, some seventy are gardeners' Pelargoniums (Pelargonium, section Pelargium of Harvey), and 28 are of the Ivy-leaved series.

The Ivy-leaved Geraniums are very graceful trailing plants, with a bright scarlet flower, or one with tints running toward the light red and orange scales. The modern growers show a preference for the double-flowering varieties, following doubtless the demand of the public—a choice fully justified by a comparison of the ample, well-clothed modern flower with the more scantily furnished older type. The ivy-like leaves, the grace of their trailing habit and the pretty flowers make this variety a charming plant for the hanging basket or for any spot where the trailing plant can be used with advantage.

The tradition receives an apparently unanimous assent that all the hundreds, we might say thousands, of varieties of Zonal Geraniums are descended from two parent races—the Pelargonium inquinans and the Pelargonium zonale—imported from the Cape of Good Hope and grown in England as early as 1710 and 1714 respectively. These have been crossed and recrossed with each other and with their descendants to such an extent that a European-cultivated flower can no longer be found that represents either of the parent types. A mixed race has been produced, the Zonal-inquinans. In 1732 there were alive in Sherard's gardens at Eltham, England, six species of Pelargoniums. The first edition of *Le Bon Jardinier*, that of 1773, published at Paris, mentions but three sorts. A recent catalogue of Cannell, the English grower, contains the names of upwards of 700 varieties; one of Bruant (Poitiers, France), upwards of 900; and a little book by H. Dauchenay, published this year at Paris, treating only of the Zonal-inquinans race, contains the names of more than 3,500 varieties, many of which have, of course, disappeared from cultivation.

The type of Geranium best known on this side of the

\* *Abies nobilis* (Lindl.), Engelmann, Brewer & Watson, *Bot. Cal.*, ii., 119 (1880), in part, so far as relates to "the Red Fir of northern California forming large forests about the base of Mount Shasta."

Atlantic is that of the double-flowering Zonal-inquinans varieties, perhaps on account of their qualities as bedding plants. Here, in accordance with the demands of modern taste, to the old scarlets, often very vivid, have been added, in the coloring of the flower, the lighter tints of red and of

orange. In the double-flowered sorts the individual flower loses character, and its importance is absorbed by that of the truss, which, whether large or of medium size, should be copiously and compactly furnished. There seems to be a preference for plants of a dwarf habit. The specimens

grown at Cornell have proved, as a rule, to answer to the descriptions in the catalogues, and intending buyers may be safely directed to them for the choice of the color of flower and habit of plant they prefer. So, too, with the variegated-leaved Zonals, including the bronze Zonals. But few of these latter are included in the Cornell collection. The flowering ones are interesting, in that their flowers are of the primitive, narrow-petaled type, and a comparison of them with the productions of later years furnishes a comparison of the advance made. This consists mainly in the rounding and enlarging of the general form of the single flower and the filling out of the petal, so that now the petals almost completely overlap and the intervening spaces have disappeared.

As early as 1841 *The Gardeners' Chronicle*, of London, in congratulating the public upon the advance already made in the Zonal Geranium, said: "The long, narrow, flimsy petals, moved by every breath of wind and separated to their very base by broad open space, have been succeeded by the beautiful compact flowers of the present day, with broad short petals, so entirely overlying each other as to leave scarcely an indentation in the outline of the flower."

The illustration on this page shows the flowers which *The Gardeners' Chronicle* then set before its readers. It has to do, perhaps, with the success of the English growers that they should at so early a period have had before them a distinct ideal. Moreover, it is interesting to note that the English and Continental types tend toward the same ideal of beauty, so much so that Monsieur Dauchenay, in the book already referred to, has to choose other characteristics than those of the flowers to distinguish between certain of the races. If a first place must be given to races, several of which produce such beautiful individuals, it will probably be awarded to the English round-flowered varieties, brought to their present perfection by Cannell, Pearson and other English growers. They are beautiful in the size and symmetry of both truss and individual flower, and especially in the lighter tints of the red and of the orange scales. And yet, if after having looked at a group of these flowers the eye happens to fall upon one composed of the masterpieces of the French growers—Bruant, Lemoine and others—this judgment is apt to be questioned. If we may take the Cornell collection as a fair representative of both, we will say that the English have attained great beauty in the lighter tints, and that the French, while not behind in these, have produced some reds which for depth and brilliancy are superb. There is, by the way, probably no floral subject to which these superlative terms, so much misused, can so often aptly be applied as to the modern Geranium flower.

An interesting introduction of the French are the "Panache," or "splashed" series. In these the various tints of red are underlaid or mixed with white in the most diverse manner, sometimes producing the effect of mere spots of one color or the other, sometimes that of a gradation from a light tint to a deep shade running from the centre to the tip of the flower, or vice versa. An interesting morphological development, and a somewhat uncommon one, is that of the umbellule. A single flower of an

umbel is raised above its companions by a stem that has lengthened into a short stalk. As to the symmetry and size of the plants themselves, those in the Cornell collection are too young to allow of safe judgment. As the plants began to flower, a feeling of disappointment was quite general, which can hardly be explained now that it has yielded to one of admiration. Perhaps the long stalks of the flowers shocked at first; perhaps the first colors to develop were the least pleasing. In any case, if there is a fortunate difference in opinion as to the relative beauty of various flowers, there is none as to the beauty of the collection as a whole.

It would be invidious to recommend particular flowers among so many beautiful ones; and, again, the intending purchaser may be sent to the catalogues of the reputable growers for the color and habit of their choice. If the Zonal Geranium is a somewhat formal flower, it cannot be said of the simple-flowering varieties, as it can of the double-flowering sorts, that the individuality of the individual flower has been merged into that of the truss. As to color, the range is not wide, embracing as it does only the scales of red and orange, and running to white; yet, within these limits, it is very rich, offering from a pure white or the mere suggestion of a tint or an iridescence, to the deeper tones of its characteristic lines. Who knows but the Zonal Geranium may sometime become as favorite a flower here as it is in England, whence the London correspondent of *GARDEN AND FOREST* could write a few years ago (*GARDEN AND FOREST*, November 28th, 1894), referring to Mr. Cannell's autumn exhibition of Zonal Pelargoniums: "They are as delightful to look upon as is the return of spring. . . . I question if there is anything in the whole range of garden exotics which has the same all-round value as the race of Scarlet Geraniums?"

## Cultural Department.

### The Hippeastrums.—III.

#### HYBRIDS.

IN the days of Dean Herbert many fine hybrids of *Amaryllis* were raised, which, however, were mostly lost again. About a hundred of these were described and many were figured in the second edition of Sweet's *British Flower Garden* (1830). Dean Herbert, in his excellent work, *Amaryllidaceæ* (1837), enumerates and gives the parentage of thirty-one of the finest hybrids raised by himself and others. The first hybrid of which we have any knowledge is *Hippeastrum Johnsonii*, raised by Mr. Johnson, an amateur, in 1810, from *H. Regiæ* and *H. vittatum*. It is very robust, free-flowering and beautiful, and still the most common of all *Amaryllis* in cultivation. A lover of *Amaryllis* usually starts with this one when forming a collection, as it is easily grown, and it is not uncommon for it to flower twice a year. The fragrant, showy flowers, of which four to six are carried on a scape about eighteen inches high, are deep cherry-red, banded with white. Scarcely any other flower is so frequently seen, and in such prime condition, in windows and gardens as this *Amaryllis*. Its abundant deep green strap-shaped leaves are usually fully developed when the large trumpets open. In the Gulf region it is one of the most common and highly prized garden flowers. It flourishes luxuriantly in the open air as far north as southern Missouri and the City of Washington, but requires a good winter protection of ashes, sawdust or leaves. In the south it forms in a few years large clumps which often produce twenty to thirty flower-scapes at the same time and make beautiful masses of bloom. This robust hybrid is a good example of the survival of the fittest, as all the early weaker-growing kinds were lost soon after their introduction.

Another noteworthy cross still in cultivation is *H. Ackermannii*, raised in 1835 from *H. aulicum* platypetalum crossed with *H. psittacinum*. It is of fine open form and marks a great advance on all its predecessors. A few years later *H. Ackermannii pulcherrimum* was obtained from *H. aulicum*, crossed with *H. Johnsonii*. Its beautiful, symmetrical form and good substance, in addition to its dazzling red color, gave a considerable impulse to the culture of these wonderful bulbous plants.

I have before me three colored plates of *Amaryllis* published in *Flore des Serres* about forty years ago, each plate showing four different hybrids raised by the late Louis van

Houtte, of Ghent. Although pronounced as the very best *Amaryllis* of their time they would scarcely attract more than a passing glance to-day. They all show unique and often brilliant colors, but all are characterized by narrow, pointed segments, scarcely broad enough to exclude the light from behind. At the same time Van Eeden took up the cultivation of the *Amaryllis* with marked success, as his fine hybrids H. Count Cavour and H. Fidelio show.

S. A. De Graaf, of Leyden, Holland, is usually termed the *Amaryllis* King. He has raised and introduced many thousand exquisite, broad-petaled and finely formed robust-growing hybrids. These plants have been cultivated in the family of Mr. De Graaf since 1790. At first only the species were crossed and intercrossed, and though rich colors were obtained, the flowers were small. The present Mr. De Graaf began to hybridize in 1862. From a fine hybrid named after his family, H. Graveana and H. psittacum, the very robust and strikingly beautiful Empress of India was raised. This hybrid is of glowing orange-scarlet color, with broad white bands, changing in the tube to a yellowish green. The segments are very broad and the flowers are of gigantic size, measuring about eight inches in diameter. With the appearance of this remarkable hybrid a new era in hybridizing *Amaryllis* began. All the sorts now sent out by Mr. De Graaf are stately in growth, exceedingly rich in color and of fine form. Bulbs fifteen to eighteen inches in circumference are produced, as a rule, each bulb sending up from two to four flower-scapes, each crowned with four to six flowers. Of the following almost all vie in beauty with Empress of India: Professor Koch, Van Speyk, Jacob Cats, Franz Hals, Laurens Koster, Rubens, President Carnot, Mozart, Louis Pasteur, Willem III. and Surprise. Of the light-flowering hybrids the following are the most beautiful and robust: Elvira, Waterloo, Conqueror and Schiller.

The introduction of H. Leopoldii and H. pardinum afforded an excellent opportunity to Messrs. Veitch & Sons, of Chelsea, England, to attempt the improvement of the beautiful hybrids raised by Mr. De Graaf. In 1867 they raised the very glowing broad-petaled Chelsoni and Brilliant. Unfortunately these forms are weak growers and not easily kept in good health. Later, Mr. John Heal, who is in charge of the great *Amaryllis* collection of Chelsea, crossed De Graaf's Empress of India with the best forms of Leopoldii, with the result of obtaining not only four to six flowered scapes, but also decided breaks of color into various shades and tints, and from the intercrossing of forms so obtained has resulted the race of *Amaryllis* now so universally admired. Almost all the named *Amaryllis* sent out by Messrs. Veitch at present are of the most symmetrical form and as beautiful in every respect as any Lily. I have just now the following in bloom: Crown Princess of Germany, very short-tubed, open, broad-petaled, rosy white clouded with deep glowing red; John Heal, deep red with a yellowish white star and points of segments broadly tipped, creamy white; Milton, Meteor and Enchantress, all of a light color lined and penciled with red; Southey, Star of India and Ne Plus Ultra, all of vigorous growth and bright red color.

A little later Mr. B. S. Williams, of London, also began the hybridizing of *Amaryllis*, but on an entirely different line. His results are among the best achieved. He succeeded in raising the exquisite *Amaryllis*, Dr. Masters, a small-flowered but exceedingly gorgeous hybrid, a glowing crimson-scarlet self, without a trace of any other color. This kind is easily grown, and flowers profusely when very small, in the window as well as in the greenhouse. Mr. Williams has also raised robust-growing, large-flowering hybrids, of which Lady Ardilaun, Joseph Chamberlain, Ornata and Magnæflora are fine examples, but he especially excels in the smaller-flowering, symmetrically formed kinds, particularly those flowering in autumn. These have mostly been derived from *Hippeastrum reticulata* and its progeny, and almost all have short broad leaves, striped with a conspicuous white band. Of these Mrs. Garfield, Mrs. William Lee, Comte de Germiny, George Firth and R. J. Pitcher are the most beautiful now in cultivation.

One of the best *Amaryllis* cultivators and an excellent writer on the subject is Mr. James Douglas, of Great Gearies, England. He has a fine private collection and has raised a number that rival in gorgeous coloring those obtained by Mr. John Heal, of the Messrs. Veitch. I have quite a number of his kinds in my collection, and all are beautiful. The most noteworthy are Serapis, Clarinda, Cleanthes, Prince Albert Victor, Grand Monarch, Great Gearies, etc. His accounts of these royal plants in the English horticultural journals have done much to disseminate information on the subject, and many flower lovers have been induced by him to take up their cultivation.

Milwaukee, Wis.

H. Nehrling.

## Early-flowering Shrubs.

GARDEN AND FOREST has often called attention to the beauty of the foliage of trees in early spring, not only on account of its delicate texture, but on account of its wonderful color, which is different in every species and sometimes in the individual trees of each species. It often changes between morning and night through a range of color entirely different from that which the same leaves assume in autumn. Of course, these spring tints are not as vivid as those of autumn, but they are quite as rich, and our forests never show more wonderful variety of tone than they do through the hazy air of early May. But I do not remember ever to have seen much stress laid on the varying colors of the foliage of shrubs in spring, although this is almost as beautiful, and it adds one more to the many delightful aspects of the shrub border. For general form, for luxuriant flowering, for variety of foliage, for beauty of fruit in summer and winter, for the depth of the color of its foliage in autumn, much has been written about shrub plantations, but it well may be added that between the middle of April and the last of May the variety of form and color in the leaves of any extensive plantation of shrubs brings a constant delight. The light yellowish green of some of the low Willows, the gray of the *Elæagnuses*, the dark bronze or deep wine-color of some of the *Viburnums* with all shades of green between, make a variety which is almost infinite.

This is the flowering season of many shrubs; the very earliest of them, like the Chinese Bush Honeysuckles, *Lonicera fragrantissima* and *L. Standishii*, are already past their bloom. So are the Spice-bush, the beautiful Cornelian Cherry, *Daphne Mezereum*, the Leatherwood, *Andromeda floribunda* and its Japanese relative. Several of the Currants are still in flower, and among them the western *Ribes sanguineum*, which is occasionally seen here, though it does not do as well as *R. aureum*, the well-known Missouri Currant, with its bright golden-yellow flowers. The hybrid *R. Gordonianum* is very hardy, being a cross between *R. aureum* and *R. sanguineum*, and bears flowers abundantly in racemes. There are many other varieties and species of Currant which ought to be in gardens and which are found in collections like the one in the Arnold Arboretum. For example, the American Red Currant, *R. rubrum*, is a beautiful object when in flower. Out in the swamps the fragrant *Andromeda polifolia* is in bloom, but it is rarely seen here in cultivation, although it does just as well in a border and flowers as freely as it does when it is in the peat bog where it naturally grows and is sometimes almost entirely submerged in water. The little Swamp Laurel, *Kalmia glauca*, a low shrub from the far north, is just opening its lilac-purple flowers, and so is the beautiful *Rhodora*, which is known by Emerson's poem to a very great many people who have never seen its rosy flowers in a cold northern swamp. *Rhododendron Vaseyi* is showing its clear pink flowers, which are quite unlike either of those of other Azaleas. Many years ago GARDEN AND FOREST recommended the crossing of this plant with the *Rhodora*. Has any one tried the experiment? The Siberian Pea-tree, *Caragana arborescens*, and the shrubby *C. frutescens*, which begins to flower a day or two earlier, are both now showing their bright yellow pea-shaped flowers in clusters from the axils of the leaves. *Daphne Genkwa* is displaying its tubular flowers with the singular bluish-lilac color which no hardy shrub of the season exactly matches. *Spiræa Thunbergii* has passed out of bloom, the old-fashioned *S. prunifolia* is still covered with its double flowers and will soon be followed by half a dozen more, while *Exochorda*, often called the Pearl Bush, Japan Quinces in variety, *Rhodotypos* and many others are in full beauty. Among the smaller trees the Red-buds, many of the Plums and a wonderful variety of flowering Apples and Thorns are in full bloom. In short, the shrubbery is never more beautiful than it is in early May.

New Brunswick, N. J.

R. Ennis.

## Orchids in Flower.

THE greenhouse is as gay with flowers in April as in any month of the year, and the Orchid-house quite holds its own, with most of the genera represented. Cattleyas are probably most numerous. Fine forms of *C. Trianae* are in flower, and one of the most distinct is the variety *Schröderiana*. *C. Lawrenciana* is bearing some handsome spikes of five and six flowers. *C. intermedia*, *C. Skinneri*, *C. Mendelii* and *C. maxima* are all in full flower, while the flowers of *C. Mossiae* are just pushing through the sheath.

Among *Dendrobiums* a few flowers of *D. nobile* still remain, while *D. densiflorum* and *D. thyrsiflorum* are just coming to their best. Fine flowers of the fragrant *Cymbidium chrysanthum* are still to be seen.

Cypripediums are not so plentifully represented at this season. *C. villosum* will soon be past its best. *C. Lawrencianum* is just coming in, and this deservedly popular variety is attractive both in flower and foliage. *C. caudatum*, or *Selenipedium caudatum* as it is now classed, is bearing some fine flowers, which, with their long tail-like petals, are more quaint than showy.

The somewhat rare *Bifrenaria Harrisoniæ eburnea* is bearing its two-flowered spikes of ivory-white flowers. A few flowers of *Lycaste Skinneri* still linger, though somewhat out of season. This is one of the longest-standing Orchids we have if taken care of, but the least touch disfigures it, and it must, therefore, be carefully handled. *Odontoglossum Harryanum* is carrying some fine spikes, while the little *O. Rossii* and its variety *O. Rossii majus* still produce a few flowers. *Oncidium splendidum* is just at its best and is bearing noble spikes of richly colored flowers. The flower-spikes of *Renanthera coccinea* are fast pushing out, and an abundance of bloom is promised. Several varieties of *Phalænopsis* are still in flower, *P. amabilis* and *P. Schilleriana* being most abundant. *Schomburgkia undulata* still holds its brownish purple flowers in good condition, but they will soon be past their best.

Tarrytown, N. Y.

William Scott.

**Irises.**—To continue the calendar of Irises, *I. fumosa* in mid-bloom now proves to have a flower of a light yellow color more pleasing than *I. Caucasica*, with a little smokiness, but it is not a very effective garden plant. In foliage and habit it is akin to *I. Sindjarensis*. The first of the rhizomatous Irises flowered last week. *I. rubro-marginata*, which I have before described as a very dwarf species with scythe-shaped leaves and small flowers an inch across, dark red-purple, tinged with blue, in color. It has tall and large standards. It is a bearded Iris from Asia Minor. Other Irises now in flower are *I. pumila* and its white variety, both dwarf kinds, six inches or so in height; also *I. Chamæiris*, a species growing about a foot high, with pleasing yellow flowers. About the same height is *I. Olbiensis*, a dark purple-flowering kind, very desirable and effective. Somewhat dwarfer is *I. lutescens*, with pale yellow flowers and falls slightly tinged with purple; from a garden point of view, an inferior species. Similar in habit and size is *I. Statellæ*, a species with creamy white flowers and yellow markings on the falls. The color is very pure in tone and the species one of the most desirable. Also at this time flowers *I. Tectorum*, the Japanese Roof Iris, though it is under protection, and has never been tested for hardiness in my garden. It flowers before it has made much new growth. The flowers are very handsome, with wide falls light lavender in hue, darker markings of the same color. This Iris has a very pretty habit, the sword-like leaves being somewhat relaxed. My plant produces double flowers, if that describes the curvature, which may be its normal form, or otherwise.

## Correspondence.

### Bibliographical Notes on American Trees.—II.

To the Editor of GARDEN AND FOREST:

Sir,—In No. 477 of GARDEN AND FOREST, Mr. Farwell calls for a more explicit statement of the case of the publication of *Abies* as a genus by Duhamel in 1755. He credits me with saying that "Duhamel published a genus *Abies* in 1755," but complains that I "fail to state what his type was." It is true that I did not indicate what was Duhamel's type; but that was not and is not necessary, inasmuch as I did not publish any such ambiguous statement as that Duhamel presented a genus *Abies*. I said the genus *Abies*; and that expression implies that the author has the Firs, not the Spruces, for his type. Of course, all early authors included the species of *Picea* and of *Tsuga* under *Abies*, Duhamel with the rest; but they are quite as unanimously accepted the true Firs as the type of *Abies*. In this Duhamel is even more explicit than some others, for, in characterizing *Abies*, he states that the more genuine species—the *Abies* proper—have upright cones, two-ranked foliage, etc. And then, in the enumeration of the species, the common Old World Fir, *Abies alba*, Mill. (*A. pectinata*, Lam.), holds the first place, as being the type of the genus.

In attempting to establish the identity of Miller's *Abies Canadensis* with the *Pinus Canadensis* of Linnæus, Mr. Farwell has at least presented a curious, if not, indeed, a very difficult problem in nomenclature, though his own way of solving it will not satisfy every one. In the process of his reasoning

some important considerations seem to have been left out of view, as, for example, the possibility that both Linnæus and Miller may have had two different trees, perhaps of different genera, included under the specific name *Canadensis*. For, if it be admitted that Linnæus' descriptive phrase, "*foliis solitariis linearibus obtusiusculis submembranaceis*," applies to and indicates the Hemlock Spruce, it is more certain that the synonym which he adduces from Miller, and which ends with the character "*conis parvis biuncialibus laxis*," cannot belong to the Hemlock Spruce; for the cones of this are not "lax," nor are they even one-half of "two inches long"; but this, the essential character, does apply to what Miller calls the "Newfoundland White Spruce Fir." It is quite conclusive, then, that our White Spruce forms a part, at least, of the *Pinus Canadensis*, Linn., and if the Hemlock Spruce was at all intended by him, under the name *P. Canadensis*, then his so-called species of that name is made up of two trees of different genera—a situation in which that celebrated author placed himself upon almost every page of the *Species Plantarum*. It is even possible to think that by his *P. Canadensis* nothing at all but the White Spruce is intended. Miller, a contemporary of Linnæus, a careful botanist, and particularly interested in trees introduced from America into Europe, had not the remotest suspicion that the *P. Canadensis* of the *Species Plantarum* meant anything but the White Spruce. Linnæus had cited his figure of it, published in 1760, as a type, and he himself in 1768 seems innocently to have returned the compliment by adopting, and giving the first place to, Linnæus' descriptive phrase. If by that phrase anything else than the White Spruce had been intended, Miller was completely unaware of it. And as for the Hemlock Spruce, it is plain that Miller, in naming and publishing it as *Abies Americana*, believed himself to be naming a tree of which Linnæus had made no mention. When, therefore, it is proposed, as by Mr. Farwell, that the two names, *P. Canadensis*, Linn., and *Abies Canadensis*, Mill., must be received as applying to the same species, we are ready to answer: Yes, unless under each name two species are included. But when it is said that both names apply primarily to the Hemlock Spruce, we are obliged to protest, first, that Miller both implicitly and expressly denies that he had such intent; and second, that it remains to be shown that even Linnæus meant, by *P. Canadensis*, the Hemlock Spruce.

Catholic University, D. C.

Edw. L. Greene.

### Is the White Pine Doomed?

To the Editor of GARDEN AND FOREST:

Sir,—I have been interested in the discussion of this question in your columns, and I will leave the scientists to decide whether coniferous forests must ultimately give place to those of deciduous trees. In my experience I have found species of both classes of trees which it seemed to me must fail sooner or later because they are unable to produce seeds of good germinating quality, but the White Pine is not one of these. When I lived in Vermont fifty-nine years ago they were cutting timber on Woodford Mountain, adjoining Bennington, for charcoal. An old Vermonter surprised me by saying that wherever a forest was cut down a new kind of timber was sure to take its place. This was the first time I had heard this statement, though it was by no means the last, and when I asked him where the seed came from he replied that he did not know. White Pines are trees which I have admired more than any others, and I have watched them during all these fifty-nine years. In that period I have traveled among White Pine forests in New England, both Canadas, Michigan and Minnesota, and it never once occurred to me that White Pine was losing its power to reproduce itself from lack of seeds, and while I have planted seeds of this tree and sold them for both the home and foreign market, except in a single instance, I have never found any difficulty in securing all I wanted. In that case I sent to Germany and bought eight hundred pounds of seed that had been shipped from Halifax a few weeks before. My experience is that a White Pine-tree will average a full crop of seed once in three years. One year the tree will be well filled with embryo cones, the second year it will perfect a good crop of seeds, and the third year it forms buds for the next crop. I have seen White Pine-trees cut down in Vermont to clear up a farm, and when I visited the same place forty years later I have found the farm run out, while the few Pines that had been left among the rocks on the mountain side had filled the rough places with saplings and seedlings. Several years ago we had an application from a German seedsmen for forty hundredweight of White Pine seeds—that means 112 pounds to the hundredweight and 20,000 seeds in every

pound. A Vermont man secured the order and he is probably shipping from there yet. Around Hanover, New Hampshire, an immense quantity of this seed could be collected, and upon the whole, my experience is that the White Pine is spreading over land where it was not known a century ago.

Many years ago Burnet Landreth wrote to me to say that on some land he owned in Virginia there was a large White Pine-tree which he thought had grown from seed dropped accidentally and this had seeded the land to a wonderful extent all about it. I met with a greater surprise than he did when I went to North Carolina to plant three hundred acres of White Pine on the Vanderbilt estate. Right in the city of Asheville on the hillside stood two White Pines on a steep bank, and these had seeded the long slope with Pines up to twenty feet high, and in several months' leisure I had there explored a great part of the mountains of western North Carolina and eastern Tennessee, and found White Pines in groups here and there, and in many places in uncultivated hills, and in no instance did I notice a sign of very old or decayed trees.

On our sand dunes where there were hundreds of large trees when I came here fifty-three years ago, straight White Pine logs were used by the settlers to make houses and barns, and the gnarly, stunted trees that were there then still stand and produce seeds freely, and seedlings, too, but these are burned up by fires which run over the ground almost every year. Now, these White Pines in Tennessee and Carolina produce seedlings in wonderful quantity and they are of all ages, while the Tulip-tree, although growing in abundance everywhere, produces very few seedlings, and these are separated by ten or a dozen years of age. We have had samples of seed of the Tulip-tree from Indiana, southern Illinois, Kentucky, Tennessee and North Carolina, and we have never found more than ten per cent. of it of germinating quality. All the while I was at Mr. Vanderbilt's place we could find no seedlings, or, at least, very few in a long ramble, except in one instance where a tree had been broken nearly off at about ten feet from the ground with the top still attached. There we found about a thousand seedlings three years old. Perhaps this experience may help some one in theorizing on this interesting problem.

Waukegan, Ill.

### A Wholesale Market for Cut Flowers.

To the Editor of GARDEN AND FOREST:

Sir,—One of the principal wholesale markets for cut flowers in this city besides the Cut-flower Exchange, on West Twenty-third Street, and the wholesale commission dealers, is the one at the foot of Thirty-fourth Street, on the East River. Here about 150 growers come each morning throughout the year, including Sunday. The first sellers and buyers are on hand as early in the morning as five o'clock, but six o'clock is announced to be the opening hour after June the first. The floor of the second story used for the market measures, perhaps, 100 by 50 feet. Space on counters along the walls and in the middle of two large rooms is let at the monthly rate of sixty-five cents a foot to stockholders of the concern, and seventy-five cents to non-members, four feet being the average space rented. Growers come from fifteen to twenty miles out on Long Island, from College Point, Bayside, Great Neck, Floral Park, Woodside, Newtown and other sections. Germans predominate among the sellers, some of whom have attended these sales since their establishment, about twenty-five years ago, and among the buyers are many Greeks, with English-speaking women and men, who have street-stands and small stores of their own. While most of the customers are of these classes, representatives of some of the best stores in New York and Brooklyn come here for any chance novelties and flowers of specially good quality. These early sales are a convenience to small dealers, who can buy the day's stock and have it on their premises by eight o'clock, before the Cut-flower Exchange and commission men have begun business. The early hours here are, however, a disadvantage during midwinter, when buyers do not find it easy to start out before daylight, and the wholesale markets are thus brought into more direct competition, with the effect of lowering prices here. After April the earlier hours are appreciated, as improved prices indicate. At this time of year the main business is done from six to seven o'clock, when a babel of languages is heard. The stock is brought to town by trolley and train, and is carried in large oblong baskets or in great arm-loads. During the Chrysanthemum season and at Easter, the busiest times of the year, two or three persons are often needed to bring the product of one establishment, but it is astonishing how much is packed into one basket and how tightly the flowers

are bunched without showing injury after they are opened up. A large basket, with the enforced capacity of a good-sized trunk, and an armful of ten dozen chrysanthemums or lilies are readily carried by one person. The retail city trade on Saturday regulates the volume of Sunday morning purchases here, but, as a rule, only about one-third as much trade is done then as on week days.

On a visit on Saturday morning, May 8th, a great variety of the cheaper homelike and familiar flowers was noted. Candytuft, long, luxuriant stalks of white Snapdragon, Stocks, Sweet Alyssum, Mignonette, Geranium-leaves, Chinese Narcissus, *Narcissus poeticus*, Lily-of-the-valley and other bulbous flowers; Forget-me-not, Marguerites, Sweet Peas, Heliotrope, Lilac, Bermuda Lilies, Carnations and hybrid Perpetual Roses were the staple stock. Neat bunches of wild Violets were offered at sixty cents a dozen; attractive bunches of the dainty and fragrant *Daphne Cneorum*, of about two dozen stems, at \$1.50 a dozen; callas at fifty cents a dozen, and the best Harris lilies at the same rate. Only a small percentage of the carnations were of high grade, and while these sold for \$1.50 a hundred, \$1.00 was a general price, and short-stemmed flowers were offered at fifty cents. The arrangement and display of the flowers showed little of the taste and skill which are seen in the markets where more choice and costly flowers are sold, and had the suggestion of out-of-door flowers from a country garden rather than of flowers grown under glass with the highest art and best appliances. For example, it was not uncommon to see three distinct and conflicting colors of carnations in one bunch of a hundred. To be sure, this variety of kinds in a small quantity made a more salable package to offer to small dealers, and, as the object of the market is to sell flowers, no reasonable fault can be found with want of æsthetic arrangement. The range in quality of roses was most marked, and, besides *Perle des Jardins*, *Bride*, *Bridesmaid* and other similar varieties at a dollar a hundred, included the same sorts at three and four times that amount, and *Ulrich Brunner* at \$1.50 and \$2.00 a dozen. There were occasional offerings of the old *Lamarque* rose at low prices, and considerable quantities of well-grown moss roses at \$1.50 a hundred.

Primulas were seen more rarely, and showy Parrot tulips, yellow centaureas, trusses of hydrangeas, branches of flowering Almond, *Astilbe*, *Deutzia gracilis*, *Genista*, double-flowering Peach and *Spiræa Thunbergii*. Buds of the richly colored *Pæonia tenuifolia* in their fine foliage made a pleasing effect on the eye, though a quantity of these flowers indoors has a disagreeable odor. Spikes of gladioli were seen once or twice, and of *Cymbidium eburneum* and a *Dendrobium*. *Funkia*, maiden-hair fern, asparagus and smilax were quite abundant, and several dealers sold only remarkably fresh-looking polypody and common brake, *Pteris*, gathered in the Catskills last autumn. By eight o'clock the last flowers had changed hands and been transferred to the baskets of buyers, and the departing throngs with filled and with empty baskets seemed strangely like those which had arrived a couple of hours before.

New York.

M. B. C.

### Spring Notes from Germantown, Pennsylvania.

To the Editor of GARDEN AND FOREST:

Sir,—I have observed that the color of flowers seems to vary in different years, as if the special qualities of a given season had some influence in this matter. It is noticeable hereabouts that the flowers of the pink Dogwood are of a much deeper color this spring than usual. The foliage of what is known as the Blood-leaved Japanese Maple is also darker than usual, and these small trees were never more striking than they are now. In secluded nooks along the Wissahickon the rocks are all ablaze with the flowers of the Wild Columbine. How can these plants flourish with so little apparent nourishment? They not only grow, but they grow with great thriftiness out of crevices in the rocks where there is scarcely room enough for their roots and where it seems impossible for any soil to enter.

Among our most beautiful trees just now are the Crab Apples of various kinds. The variety known as the Transcendent has especially large white flowers, which are very fragrant, but the flowers of all the varieties are beautiful and abundant; their fruit, too, is ornamental, and much of it is excellent for jellies and the like. The so-called flowering Peaches, too, are particularly beautiful just now, a variety with crimson flowers being specially effective. Lilacs are slower in opening than usual, and this gives an opportunity for *Syringa oblata* to show its special qualities of earliness, as its flowers expanded in advance of all the forms of *Syringa vulgaris* by a

full fortnight. Many Crape Myrtle plants in Germantown which were left outside have come through the winter with little or no injury. It is observed that after these plants have passed through one season safely they are less susceptible to injury the next, and appear to increase in hardiness after they have stood out several seasons.

Germantown, Pa.

Joseph Meehan.

### Notes.

During April 305,160 bunches of bananas were sold in New York city, mainly from Port Limon, Aspinwall and Jamaica.

It has been suggested that instead of the present plan of distribution of free seeds by the Government that the Department of Agriculture should issue legal-tender notes which Congressmen could distribute among their constituents, so that each one could purchase the particular kind of seeds or flowers or shrubs or trees he needed. Why not?

Two months ago we noted the first arrivals for the season of apples from Tasmania in the English market, and stated that, perhaps, as many as 100,000 boxes would be shipped to the United Kingdom during the year. That limit has been already passed, and double the amount will probably be received before the season is over, which will not be until well into next month, when apples of the current year from the northern hemisphere will be on sale.

A plot owner in the Cypress Hills Cemetery, Brooklyn, has been awarded damages from the Cemetery Association in the sum of \$3,500 by the Supreme Court of this state on suit brought for injuries received from Poison Ivy. The Justice, in charging the jury, held that it was the duty of officials to remove poisonous vines, and on application for a new trial, which was granted, he added that the verdict was a just one and that the plaintiff was entitled to damages.

The British Consul at Naples reports that barley is largely used at Naples in the manufacture of port wine. The grain is malted, after which the port wine bacilli are introduced into the mead, where they multiply abundantly and transform the immature beer into the richest port. After their work is finished a sufficient stock of the microbes is preserved in the laboratory for future use, and the product is then sterilized. The manufacture of a good quality of port from barley mead is certainly a new triumph of science.

Mr. E. P. Powell writes to *The American Agriculturist* that the proper way to treat Dewberries is to cover the plants in winter plentifully with leaves, and then in spring to tie them to stakes, allowing the leaves to lie between the rows, held down, if necessary, with a few shovels of earth or a few poles. The vines in this way are under the same conditions as in a natural state when they grow wild by fences. If they have this opportunity the vines will bear heavily, otherwise the fruit is liable to be only knobs and hard, half-developed berries.

Mr. Fred W. Morse, of the New Hampshire Agricultural Experiment Station, has been examining Canada wood ashes which is sold in that state, and he finds the proportion of potash so low in some of the cheaper grades that it looks as if the quality of the ashes had been deliberately reduced by partial leaching or by mixing leached ashes with dry ashes. Buyers of ashes should look with suspicion on a lot that appears excessively moist, because in such cases the potash is seldom equal to the proportion in average ashes. In the same station it has been found that Paris green is often adulterated with earthy matter, either clay or infusorial earth. Buyers of this important insecticide should use no Paris green which does not bear the trade-mark of well-known and responsible manufacturers.

The Conservator of the Forests in Australia states that there are forty-seven millions of acres in that country upon which useful marketable timber is growing, and that there are six hundred species or kinds of timber trees there. Mr. W. Botting Hemsley, quoting this in *Knowledge*, says that Mr. Ednie Brown, the Conservator, in his enthusiasm has included many trees that do not yield timber of appreciable commercial value, but if the total is reduced one-half Australia stands in conspicuous contrast with the most richly forested districts of the northern timber regions of the Old World, and rivals the coniferous forests of North America. With all this wealth in variety, almost the only commercially important kinds of Australian timber are the Gum-trees, and there are only about a score of these out of the 135 species spread over the country.

The May exhibition of the Massachusetts Horticultural Society, in Boston, was a delight to many visitors, and it was

especially interesting on account of a group of thirty seedling Amaryllises, shown by Mr. Kenneth Finlayson, gardener to Dr. C. G. Weld, of Brookline. These plants had flowered in two years and eight months from the seed, and many of them bore five or six blooms, each of great size and substance, splendid color and first-rate form. Mr. Finlayson well deserves the silver medal which he received. Another silver medal was given to Mr. William Donald, gardener to J. S. Bayley, Esq., for a variety of *Dendrobium nobile* which resembles *Sanderianum*, but which has been named *Bayleyanum*. *Boronias* and *Azaleas* of admirable quality were shown, and the *Calceolarias* were the best ever staged in Boston. Mr. Donald received the prize for these, but the collection of Mrs. B. P. Cheney (Mr. John Barr, gardener) was also admirable. *Narcissi* and *Tulips* were shown in first-rate form, and the *Streptocarpuses* shown by John Barr were of the highest merit. Bonton, the new scarlet *Carnation*, exhibited by Mr. F. A. Blake, of Rochdale, attracted much attention.

The season for so-called deciduous fruits from California, which include all except the Citrus fruits, began in this city last Friday, May 7th, with the auction sale of thirty-six boxes of cherries, at \$1.50 to \$5.00 each. The first shipment of cherries was made from Vacaville, California, on April 26th, two weeks later than a year ago. But few California oranges are now arriving, and only four car-loads came here last week, against sixty car-loads and more a week during February and March. The retail fruit-stores make a gay display now. Besides cherries, oranges and grape-fruit, choice bananas and pineapples are shown, and large and luscious field and hot-house strawberries. Among the novelties now offered are peaches from Newport hot-houses, at \$1.00 each; hot-house grapes, from the same place, at \$4.00 a pound, and small muskmelons, from Boston, at twenty-five cents each. The first watermelons, from Key West, sell for \$2.00 each, and with these new-crop products *Easter Beurre*, *Winter Nelis* and *P. Barry* pears are seen; these cost from \$1.00 to \$1.50 a dozen. No less attractive than the fruits are the celery, mushrooms, asparagus, cucumbers and brilliant and perfectly formed tomatoes shown in the fancy-fruit stores.

The last issue of *The Garden* which has come to hand contains a beautifully colored plate of a variety of *Primula obconica*, which is really a selected form of the strain known as *Grandiflora*, with flowers twice as large as those of the species originally introduced, and of a light lilac or lavender color. The note which accompanies this picture states that this species so far has refused all attempts at cross-breeding, and, although the Messrs. Veitch have devoted much time and effort to it, no actual hybrid between *P. obconica* and any other species has resulted. Seedlings, however, have varied much in size, shape and color, and have improved much under selection. There is an especially beautiful one known as *Rosea*, the name indicating its special tint, which is said to be a great acquisition. This is really one of the most useful and popular plants which have been introduced in recent years, but care must always be used in handling it on account of the irritation and inflammation caused by its hairy glands. We believe that this fact was first brought to public attention by *GARDEN AND FOREST*, where the unpleasant results from careless handling were described as long ago as May 2d, 1888 (vol. i., p. 118; vol. ii., pp. 94, 154, 286). Sometimes this irritation causes a serious illness, but it can be prevented if the plants are always handled with gloves.

The *Northwestern Lumberman*, in speaking of the great flood in the Mississippi valley, says that the deluge has so far subsided that lumber will soon begin to move northward again over the overflowed region, but much of it will be unfit for shipment because it has been under water and is covered with silt. This dirt-covered material will all need to be cleaned, and this will involve a vast amount of work and expense. Where the cottonwood has been covered with water it will be practically ruined, as the dirt can hardly be washed out of its fuzzy fibres, and the result of this is seen in the fact that the price of this lumber has advanced one dollar a thousand. Lucky manufacturers whose lumber piles have been above the water will make the most of their advantages, and the effect will be seen in the market for oak and ash as well as for cottonwood. It will be several weeks before logging can proceed in the bottom-lands with the mills restored to running condition. There will be mud everywhere, tramways washed out, bridges and trestles destroyed, so that it will be midsummer before everything can be restored to order, with mills running steadily, and weeks more will elapse before the newly cut lumber is dry enough to ship.

## Art and Nature in Landscape-gardening.

THIS is the season when we receive the most frequent inquiries from amateur planters about shrubs, trees and herbs for what they call "decorative planting." Many persons who have lately acquired new homes in the country or in the suburbs of cities are now moved to beautify them in some way, and the first thought that occurs to every one is to secure an abundance and variety of what are known as "ornamental" plants. It is not our purpose to make out any such list, and even if we considered it advisable the season is too far advanced to begin to arrange for planting. Nevertheless, these requests suggest a word or two of counsel which may as well be repeated at one season as another. We have no novel doctrine to advance, nothing but a few principles which do not change every year like fashions in millinery.

The spring planting of trees and shrubs is practically over for the year, and where these have been planted by novices it is probable that they have been badly selected and planted in improper positions. Nevertheless, this fact is not utterly discouraging, for when once a landowner begins to take any serious interest in his home-grounds it is probable that the habit will grow on him and become a life-long and increasing source of refreshment and refinement. We have said that both planning and planting by novices are, as a rule, worse than unsatisfactory, for if there is any art which needs original aptitude, special training and long experience for the highest success, it is the art of planting public and private grounds. This statement will be admitted by most men of cultivation, but practically they do not realize its truth. An engineer or a botanist is considered qualified to plan a public garden. Places of remarkable natural beauty, when once they are acquired by a city, are often put under the control of commissioners, who may have a fair education and experience in business, and if they have in addition to this what is known as good taste they are esteemed perfectly competent to preserve these scenes, to develop their charms and to devise facilities for exhibiting them. Gentlemen of wealth who have some cultivation consider themselves quite able to lay out their own places, especially if they have the help of some journeyman gardener, who

often has no appreciation of the character and beauty of the grounds, and whose first work will be to despoil the scenery of all that makes it really valuable, and then begin the work of decorating it with flower-beds, Golden Elders and purple-leaved shrubs of various kinds. The worst part of the matter is that the men who are utterly lacking in their ability to foresee what a piece of ground will look like a few years after they have set out to "improve" it, are quite unconscious of their lack of qualification, and have not the slightest idea that any such qualification is needed. Even if they were capable of taking such a look into the future, they would not be competent to pass any intelligent judgment on the result of their work. The fact is that no one but a man of genuine creative faculty can see just what elements in a landscape are the essentials that ought to fix its character, or can estimate the relative proportional importance which should be given to each one so as to produce the best combined effect and invest the whole with a charm which is distinctly its own.

This brings us again to the point that for the treatment of any piece of ground, public or private, the counsel of a landscape-gardener of recognized standing should be at once taken. The novice who insists upon improving his own grounds must educate himself through his own mistakes. If he begins at the wrong end and buys a great many more novelties and oddities among trees and shrubs than he needs, and then wanders around in his lot for a place to plant them, he will soon see that his crowded grounds have no unity of expression or of purpose. If, however, he will endeavor to set before his mind a clear and definite picture of what his house and grounds together are to look like, and will then attempt to construct his picture, he will not be led to choose a plant simply because the catalogue pronounces it beautiful, but because it is necessary to complete his idea and give expression to his thought. All this sounds very simple, but he will find it no easy task to create such a picture even in imagination. But if he has in mind a design which is reasonably distinct, and for the details of which he can give intelligent reasons, he will certainly learn some things by his experience which very few of his fellow-men understand. When he studies his house and grounds not only as a unit, but in their relation to what is beyond them, and endeavors to shut out what is distracting or unsightly and preserve within a fitting framework the view of distant prospects that are pleasing, and when he attempts to provide for conveniences in the way of buildings and walks and place them so that they do not disturb his picture, he will learn that it requires not only taste, but hard study, to solve the complex problem that he has in hand. He will learn, too, that even within the modest limits of his home acre there are chances for an individuality of plan and for a refinement and finish in the details which an artist of the first rank would not deem unworthy of his powers.

The objection is sometimes made to the work of artists in landscape that, after all, purely natural scenery is the most impressive, and the art of man can only interfere with nature to belittle it or weaken its strongest effects. But the true artist aims to help, and not to hinder, nature. Even the broadest landscape can be improved—that is, adapted to human use and enjoyment if it is treated in a reverent spirit. We do not attempt to thwart nature when we open her thickets and help magnificent trees in their development. We are working with nature if we encourage a screen of foliage deep enough to exclude the intrusion of some disagreeable object, or if we open vistas which will uncover to us the sky-line made by a mountain range. Nature alone does not spread out for us broad stretches of meadow, but if we come to her aid she will give to us all the turf we need. That is, the real artist emphasizes and intensifies here or subdues and qualifies there. He uses the art that mends nature, working in harmony with, and not against her. This truth is not thoroughly comprehended by persons who consider the true work of the land-

scape-gardener to be the planting of flower-beds and of ornamental shrubs. But, after all, it is this broad and catholic art which alone is satisfying everywhere, and which is just as useful in the preservation of the Yosemite Valley or the scenery of Niagara as it is in planning a pastoral park or the grounds about a country house.

A YEAR ago we gave some account of the farming on vacant lots in this city, carried on under the direction of the New York Association for Improving the Condition of the Poor. The experience of another year confirms what we then asserted, namely, that there are many destitute people in the crowded districts of this city who are not only willing to support themselves, but who can earn a living if they are allowed to use land which now lies idle and unproductive. These tenement-house farmers work under the instruction of experts trained and schooled in agricultural theory and practice, so that they really cultivate their land in accordance with the teachings of science. It thus happens that besides gaining some support they are actually learning an honorable trade, and learning it in a more direct and practical way than if they were attending a school of agriculture. Last year the women again proved the best farmers, and again the mothers were delighted at the opportunity of taking their children out of the stifling tenements and giving them an actual taste of country life. Besides this, it is a great advantage to people who are unskilled and unemployed to be lifted up to a place where they can think for themselves and have their dull mental processes stirred up and made helpful. As they begin to sell their material they quickly learn the important lesson that quality commands price, and as they are brought into actual connection with the working world and are encouraged to hope that they may become self-supporting members of society this schooling in the ways of actual business is invaluable. The reason why vacant-lot farmers can support themselves on the products of a comparatively small area is that they sell directly to the consumer. Small bunches of radishes, tastefully arranged and carried in a basket among the tenements, will bring two or three times as much as the same product nets the grower who sells at wholesale. How well some of these people cultivate their varied crops and how effectively they can display them was shown at the American Institute Fair last autumn, where one woman exhibited thirty-five kinds of vegetables, all well grown and all arranged with singular good taste. This collection well deserved the award it received by the unanimous vote of competent judges.

This year the work has started once more in full vigor. Provision has been made for helping a hundred families, and a hundred other applicants were turned away because it was not possible to secure land under favorable conditions. The fact that almost the entire list of vacant-lot farmers this year are novices does not show that the people who took up this work the year before became tired of the experiment because they had failed. On the contrary, it is a fact that the greater proportion of those who once cultivated vacant lots have gone beyond the need of this help. They have been encouraged and enabled to secure steady and remunerative employment, and some of them have abandoned the tenement-house regions for a life in the country. The educational feature of this enterprise is the most interesting part of it, and if it broadens out under the present judicious management as it promises to do, there is no reason why the greater portion of the vacant land that is arable and idle in the suburbs of our cities should not be brought under cultivation. The result will be not only that the necessities of many destitute men and women will be met, but these people will learn that there is a more natural and happy life for them outside of the slums, and that they can make a living in the country by using the knowledge they have gained in these summer schools of practical agriculture.

### Three New Jersey Pines.

A RATHER hurried trip through southern New Jersey for the study of forest fires, under the auspices of the State Geological Survey, recently took me, with my traveling companion, Mr. H. S. Graves, through the fire-devastated south-eastern portion of the state. Aside from the main results of the trip, which must be reserved for a report to the next Legislature, the excursion yielded the following notes on three of the New Jersey Pines:

*PINUS RIGIDA*.—The power of this tree to sprout from the stump has been well known hitherto, but it has been generally supposed that the sprouts perish in early youth, never attaining merchantable size. This ability to coppice freely is mentioned by Mr. B. E. Fernow in an article in No. 405 of GARDEN AND FOREST, but the size to which the sprouts attain does not seem to have been definitely described. Southward from Lakewood and Toms River, on the barren, sandy, burned portions of the state, these sprouts of *Pinus rigida* are exceedingly common. In the larger specimens, which commonly reach a diameter of six to eight inches, breast-high, from two to five sprouts from the same stump are usual, while those of younger growth are often much more numerous. The life and proportions of the sprouts, like those of the less numerous seedling trees with which they were associated, were so limited and restricted by the frequently recurring fires that I was able to form no judgment of the maximum size to which they may attain. In every case noted the parent stem had been destroyed by fire, not by the axe. This fact, taken in connection with the habits of this tree observed elsewhere, may indicate a possible connection between this unusual sprouting power and the sandy soil and frequent fires of southern New Jersey.

The same capacity to sprout is shown also in the very numerous suckers which cover the trunks and the trunkward ends of the branches of trees whose leaves have been completely burned off, and whose smallest twigs bear marks of fire (see page 195). I am acquainted with no other tree whose capacity to recover after such treatment compares with that of *Pinus rigida*, although I do not know how durable that recovery may be. The oldest suckers examined had been on the tree but three years.

*PINUS ECHINATA*.—So far as I am informed, sprouts of this tree have not hitherto been noted. Near New Lisbon, in the central part of the state, they were quite common, though of small size, while at Lakewood and elsewhere larger trees, which appear to be sprouts, but of which the origin is still uncertain, are often conspicuous. Great numbers of little sprouts occasionally spring from small fire-killed trees at the surface of the ground, as happens so frequently with *Pinus rigida*, and stumps bearing a number of vigorous living sprouts of some size were also found. The power to sprout from the stump has not, until now, been known to belong to any of the two-leaved Pines in America, nor have I learned of its existence among these Pines in any other region. The five-leaved Pines do not sprout, and among the three-leaved American Pines only *P. rigida* has, so far as has been reported, this power. The freedom with which in certain localities both these trees, but especially *P. rigida*, send up sprouts after a fire, leads to the suspicion that these cases may be less isolated than they appear. It seems not unlikely that further search would result in extending the range of the sprouting capacity of *P. echinata* to other regions, and possibly in finding parallel cases among species whose coppicing power is not yet recognized.

*PINUS TÆDA*.—This tree does not appear to have been reported previously from New Jersey. A single specimen, found on this trip, is growing on the Price farm at Town Bank, on the west side of Cape May, about three miles from the bathing beach and the great hotels. It stands alone, on pure white sand, two or three feet above the fresh-water lagoon, which here, as elsewhere, lies directly behind the moving sand dunes of the shore. The old

whaling town of Portsmouth formerly stood on this land, but its site is now partly under Delaware Bay and partly covered by the sands. The tree is about ten inches in diameter, breast-high, and perhaps twenty-five feet in height, vigorous, wide-spreading and evidently in strong health. Its identification as *P. Tæda* has been confirmed by Mr. Jack, of the Arnold Arboretum, who was kind enough to examine leaves, cones and fertile seeds gathered from the tree and forwarded for his inspection.

New York.

Gifford Pinchot.

### The Hardy Flower Garden.

MR. A. HERRINGTON, gardener for H. McK. Twombly, Esq., Madison, New Jersey, read a paper on this subject before a meeting of the New Jersey Floricultural Society held at Orange. The paper was illustrated by some fifty colored plates of the best hardy plants. We reproduce, in a condensed form, the more important parts of this paper:

This department of the garden has, generally, the least consideration. A lawn is laid down, a few trees and groups of shrubs are planted, and the garden is made. If the luxury can be afforded, glass is indulged in. Many gardeners understand the cultivation of Palms, Ferns and Orchids, and know the latest introductions from the tropics, but they do not grow more than a small fractional part of the hardy flora of the temperate regions, and of the improved cultivated forms known in some of the best nurseries. Even in an extensive glass establishment only an infinitesimal portion of the tropical flora can be grown, whereas in the garden numberless good and hardy plants will flourish, from the tiny Saxifrage or vernal Gentian to the stately Lilies and sturdy Sunflowers of the prairies.

In home-grounds supposed to have a flower garden one is likely to find a little assemblage of beds, in stars or diamonds and other fanciful geometric forms, and containing a limited selection of plants, mostly tender, and often clipped and pinched into formal shape. The average garden is bald and bare in spring, waiting upon the elements to make possible the planting of tender summer plants, which eventually furnish a gaudy, monotonous display, to become a mass of black decay with the first frost in autumn, while nature's great garden all about us remains beautiful weeks afterward.

Our gardens and parks need never be flowerless except when the ground is frost-bound and all vegetation is dormant. The ideal garden, and the one which can easily be realized, is one which tells the story of the advancing or declining year, and whose blossomings denote the weeks and months as they come and go. In this latitude there should be spring gardens and summer gardens and autumn gardens. In the highways and byways in early spring the resurrection of floral life may be seen on every side, and the garden should awaken in the same way. The mountain plants, whose flowers succeed the melting of the snow, and the waves of verdure spreading over hill and plain teach the practical lesson that plants in the spring garden should not be coddled and given ceaseless attention in dug-up beds and borders.

Ten years ago I tried to express in an English garden my idea of nature's planting on a grassy slope half an acre in extent, where spring-flowering bulbs were disposed. These have increased each year and now make a beautiful and satisfying stretch of blossoms in the turf from January until June. Snowdrops and Snowflakes appear first, and in February Crocuses of many colors, and spreading colonies of deep blue Scillas and Chionodoxas. In March the bright flowers of the Dog's-tooth Violets stand up in tufts of marbled foliage and seem as much at home as in their native Alps. From March until June there is an unbroken succession of Daffodils, and I noticed, two years ago, a tuft with sixteen and another with seventeen flowers where a single bulb had been planted eight years before. Other flowers in this English garden are Apenine Anemones, Grape Hyacinths, Stars of Bethlehem and Fritillaries. Every year, according to the season, there is this combination and succession of bloom for four to six months, at no outlay beyond the first cost of planting, and with no care or attention. In July the slope is mown and kept as a lawn for the remainder of the season. This happy experiment of growing flowers in the turf suggests that stretches of grass need not be cut off close from early spring onward, and that patches under the leafless trees may be charming pictures of spring. This sort of gardening is infinitely more interesting

than the ordinary practice of setting out a few beds of Tulips and Hyacinths and drilling a few Pansies and double Daisies into lines and squares. But this is only one kind of spring garden, and another, quite opposite in character, can be made from the arrangement of flowering plants which need careful and persistent cultivation. Then, too, there are many beautiful perennials for the spring garden, such as the dwarf mountain Phloxes, Saxifrages, Sedums, Aubrietias, Arabis, Alyssums, Veronicas, Silenes, etc., with Epimediums, Primulas, Pulmonarias, Mertensias, Convallarias and dwarf spring Irises. Though many of these are alpine plants and natives of rocky ledges above the tree and shrub line, they are entirely happy and prosperous in gardens under right conditions. A miniature of a mountain range should, of course, not be attempted in the garden, but a delightful effort may be had from these hardy plants in rocky beds and borders, with the rocks subordinated to the needs of the plants, instead of the too common rockery in which the plants languish and die.

A great variety of hardy flowering plants are available for making a summer garden, and a careful selection will produce a picturesque and orderly effect during the entire season, and not be a heterogeneous mingling of plants without any unity or harmony. Entire beds are planted with Cannas, Geraniums and other conventional bedding plants, and if hardy plants were used in the same extensive way our gardens would not be colorless, as they have sometimes been described. Many tender flowering plants can be used to make the garden gay in summer, but we are not dependent on them, and they should not monopolize space which could be occupied by better plants. Instead of the little pattern gardens that admit of no variety in planting, and confine our attempts at gardening to one spot, the adaptability of hardy flowers should be studied, and they should be distributed in localities suited to them. The beds should be bold and the borders long and wide, with large groups of one kind of the best hardy flowers. For example, in an Iris garden an acre in extent all of this family could hardly be included, for there are Irises from Europe, Asia, Africa and America; Irises that do well in a wet ditch bottom, and at least one Iris that will grow on the house-top, and between these extremes an endless variety adapted to every soil and every aspect. There are Pæonies, Delphiniums, Pyrethrums and Day Lilies, each of which can be massed with striking effect. Occasionally a few of them are seen dotted here and there at regular intervals, but how often has any one seen them planted in bold, simple, natural groups?

Here again nature gives a lesson for arrangement in the garden. Along the waysides flower succeeds flower on any special area, through spring, summer and autumn, and plantings should be made in the same way in the garden. Many combinations of plants whose flowers succeed each other may be used on the same plot or tract. As a practical illustration I planted last fall some of the best sorts of tree and herbaceous Pæonies. These flower early and are soon past, with only huge tufts of spreading leaves remaining for the season. If Pæonies only were planted there would be no more color for the remainder of the season, and no flowers after Pæony time. But many bright and showy Lilies flower during summer and autumn, and while these flowers enjoy the warm sunshine the roots do best in cool earth and in partial shade; consequently I planted Lilies among the Pæonies. All will grow up together, and when the flowering season of the Pæonies is passed, their luxuriant foliage will help to keep the soil cool and moist, and be an admirable support and foil to the tall Lily stems when in flower. Many similar combinations are practicable, and instead of planting an entire garden each year, some of these plantations will continue for years, increasing in extent and beauty all the while. To be successful, the soil must be well prepared beforehand. A mere turning up of the upper six inches is not sufficient. For some hundreds of feet of hardy flower border made last year we trenched the ground thoroughly two feet deep and broke up the soil below that. Manure was worked in in the proportion of about one yard to six yards of soil. With a little feeding from the surface, plants will thrive for years in borders thus prepared.

There is abundant material, too, for autumn gardens, so that they need not be made up of the languishing remnants of summer. The autumn garden of nature is a calendar of this particular time of year in masses of Golden-rods and Asters, and our gardens may be a similar record of the season. The best of the wild Asters are not to be despised as garden flowers, and many lovely forms have originated under cultivation. On the prairies are perennial Sunflowers, and in the woods and fields close at home are rich, showy Cone-flowers worthy of garden space. The native and cultivated Phloxes,

too, in a hundred good varieties, are cultivated in commercial nurseries. The brilliant and imposing Torch Lilies, or Red-hot Poker-plants, are varied in size, the dwarf Kniphofia MacOwani having spikes two feet high, while the torches of the giant *K. nobilis* are higher than the head of a man, with other sorts of intermediate height. The profuse and enduring flowers of Japanese Anemones last until they are whipped to pieces and scattered by winter winds. With all these and Chrysanthemums, Crocuses and many more, the autumn garden may be distinct from the garden of other seasons, and have a character of its own which will be individual and fresh.

A garden to be interesting need not have long ranges of glass. To be sure, cheap glass has brought within the range of modest means the growing of delicacies for the table and of flowers for home use. But the range of plants cultivated under glass does not compare with the numberless hardy ones collected from the north and the south temperate zones and from mountain ranges, not to speak of those acquired by hybridization. Cheap glass has had the effect of directing attention away from outdoor cultivation, and too often hardy perennials are spoken of slightly. The brightest and most interesting garden that I know, and which is a changing picture during nine months of the year, has no glass house, and is a forceful plea for the satisfaction and success of the hardy flower garden.

## Entomological.

### The Plant house Aleyrodes.

**ALEYRODES VAPORARIORUM** was described by Professor J. O. Westwood in *The Gardeners' Chronicle* for 1856, page 852. Its occurrence in America was not recorded until over thirty years later, and it seems probable that the species was in some way introduced into America from Europe. Inasmuch as it is now found in such widely separated localities as Michigan, Kentucky and Connecticut, we may well suppose the insect to be well distributed, at least, over the north-eastern portion of the United States.

This *Aleyrodes* is found upon Strawberry-plants in the garden, but it is more especially in the greenhouse that the insect assumes the nature of a pest. The Tomato yet remains the chief host-plant of the parasite, though I have observed the larvæ upon the leaves of the Cucumber, Potato and Lettuce growing under glass, while among ornamental plants, *Ageratum Mexicanum*, *Abutilon*, sp., and *Maurandya scandens* were attacked. It has also been reported as infesting Roses, Geraniums, Coleus and Salvia.

Toward the end of the season the *Aleyrodes* is most abundant in the Tomato-house, and vast numbers of adults are often seen flying about the tops of the plants, near the glass, where they are mating and laying eggs. On the under surface of the leaves are the silvery white, bristly larvæ, which are without power of locomotion, except when newly hatched, and they subsist by sucking the juices from the plant.

The egg is oval and slightly conical in shape, with the larger end fastened to the under surface of the leaf. Two females were observed ovipositing upon Lettuce. The beak was first thrust into the leaf, and, depositing an egg, the female swung about, with beak still inserted in the tissues of the leaf, and serving the purpose of a pivot, continuing to deposit eggs in a circle of about one m. diameter. One circle contained six, and another nine eggs. Eggs are not always deposited in circles. I have frequently found them single and promiscuously scattered over the surface of the leaf. They are of a light green color at first, but soon change to a rather dark brown, and hatch in eleven days.

The young larvæ move about for a short time, during which they find a suitable place to insert their tiny beaks, so that they, too, can suck up the vegetable's juices for their sustenance. They are there permanently fixed until the adult stage is reached. The larvæ are nearly white and more or less transparent, with the edges and dorsal surface well covered with shining bristles. When the larva is full grown it becomes a pupa without visibly changing form; a little later the skin cracks open along the back, and the

adult comes forth. For development a period of about five weeks is required for each brood. Many cast pupa skins may be found upon the older and lower leaves of the plant where the larvæ were first to mature.

The adults resemble tiny white moths and are very beautiful when examined under the microscope. Both sexes are winged. An adult has four wings, each with a single median vein. The color of the body is yellow, that of the wings white. The abdomen of the female is thicker and plumper than that of the male. The body, wings and legs are covered with a white powdery substance, which was thought to resemble flour, thus suggesting the name *Aleyrodes*, which is from the Greek *Aleurodes*, meaning flour-like. The antennæ are six-jointed.

Entomologically the *Aleyrodidae* are intermediate between the plant lice (*Aphididae*) on one hand and scale insects (*Coccidae*) on the other, and are closely related to both. In fact, for a long time entomologists classed these insects with the *Coccidae*.

The genus *Aleyrodes* has not been well studied in this country, but was monographed by Signoret some twenty or twenty-five years ago.

One species infesting the Orange-tree, figured and described by Riley and Howard in *Insect Life*, vol. v., page 219, had been named *Aleyrodes citri* previously by Mr. Ashmead.

*Aleyrodes vaporariorum* is mentioned by Professor L. H. Bailey in Cornell Experiment Station Bulletin 28, page 58, as being a pest of the Tomato-house. Professors H. Gar-

man,\* of Kentucky; G. C. Davis,† of Michigan, and A. S. Packard,‡ of Rhode Island, write of the plant-house *Aleyrodes* under the name of *A. vaporarium*. *A. vaporarium* is the correct name, because it is the one given the insect by Westwood in the original description. There is, of course, a possibility that the two insects are not identical, yet they are supposed to be the same species. The discrepancy in the spelling of the specific name is doubtless an oversight.

Fumigating with tobacco will kill the adults in the greenhouse, and this is unquestionably the best way to keep the insect in check. The larvæ upon the leaves may be destroyed by applying a solution of whale-oil soap. Kerosene emulsion is used with success against *Aleyrodes citri* upon the Orange-trees in the southern states.

The figure on this page shows the insect in the adult, egg and larval stages.

### The Hippeastrums.—IV.

#### HYBRIDS—CONTINUED

A LARGE number of gigantic hybrids of the finest form and beautiful colors have recently been introduced by Mr. E. H. Krelage, of Haarlem, Holland. Just now (April 10th) the following are in flower with me: Geier Wally, rosy white ground,

\* Annual Report Kentucky Agricultural Experiment Station, 1890, p. 37.

† *Insect Life*, vol. vii., p. 174.

‡ *Guide to the Study of Insects*, 9th edition, pp. 526 and 712.

lined and penciled with crimson; segments broad and well formed and flowers well opened, very symmetrical and large; scapes about three feet high, contemporary with the leaves; each stem bears four delicately fragrant flowers. Noble par Mérite, white ground, slightly veined and striated with red; flowers large, of good form and substance, slightly fragrant; stems thirty inches high, each carrying four flowers. Jeanne d'Arc, white, lined profusely with red, greenish in the tube; very floriferous and a strong-growing hybrid. These hybrids compare well with the others now in flower with me. They are vigorous growers and easily managed. The scapes are usually three feet high. The form of the flowers, the narrow-

belong to the less beautiful, narrow-petaled *Hippeastrum vitatum* strain, but Mr. Pfister has lately grown a large number of the vigorous kinds, using for this purpose some of the best forms raised by Messrs. Veitch and Mr. B. S. Williams. From the good hybrid Dr. Masters, fertilized with the pollen of the best forms of *H. pardinum*, Mr. Pfister has raised a large number of seedlings. Three of the finest he named Ruth, Esther and Marion. They are of symmetrical form, their ground-color is light, and they are profusely spotted and clouded with different shades of red. Like Dr. Masters, they flower when quite small. He also succeeded in raising a deep rosy flowered hybrid with only a few traces of greenish toning

Fig. 24.—New growth, one year old, on *Pinus rigida*, after the destruction of all green leaves by fire.— See page 192.

channeled leaves and color of the bulbs show that Mr. Krelage has had a way of his own in producing these grand hybrids.

In this country Mr. W. Otto Groner, of the Rock Island Arsenal, has raised the finest forms of *Amaryllis*. From many hundred seedlings he selected only four, which he named the Koh-i-noor, with very broad segments of a deep glowing red, with a greenish white star and yellowish lips; Modjeska, Barbara Pomfret and Beethoven. With the exception of the last named, these hybrids are rather hard to deal with, and great care is necessary in order to keep them in good health.

The largest collection of *Amaryllis* in this country has been brought together by Mr. Henry Pfister, head-gardener of the Executive Mansion, Washington, D. C. Most of the hybrids

at the base of the tube. This has been named Mrs. Cleveland. In the greenhouses of the Executive Mansion the beautifully foliated autumn-flowering *Amaryllis*, such as Mrs. Garfield and Mrs. William Lee, are grown to perfection.

Just now a large number of my own exceedingly vigorous *Amaryllis* hybrids are in flower. They are refined in form, brilliant in color and of a luxuriance rare among the common strain of *Amaryllis*. There is nothing in the whole floral world that can compare with these royal plants. By careful selection of the most beautiful and vigorous English hybrids that were awarded certificates of merit by the Royal Horticultural Society and the Royal Botanical Society of London, and such kinds as were pronounced the most beautiful of the Continental collec-

tions, and which are certainly the most expensive, I have succeeded in raising a strain equal and often, as I think, superior to the best forms now in existence. As the most beautiful and symmetrical kinds, such as Brilliant, Chelsoni, Madonna, Clorinda, John Heal, Mrs. Burbidge and Leopoldii, are mostly weak growers and difficult of cultivation, I only use them as pollen plants, never as seed bearers. With them the most robust hybrids are crossed, and I have been fortunate in raising strong-growing, floriferous and gorgeously colored kinds. Some came into flower in three years, and most of them in four years from the seed. It is tedious and often disappointing work to hybridize these plants, as scarcely ten per cent. will ripen their seed. In most varieties the seed-pods swell and promise to give a good harvest, but suddenly, after four weeks' growth, they shrivel and disappoint the enthusiasm of the cultivator. As a rule, the coarse-growing and valueless kinds produce seed freely.

I have invariably found that *Amaryllis* grow much better and are far more satisfactory as window-plants and in the small greenhouse of the amateur than in the great commercial establishments. They are not quickly raised and easily sold. It takes four years mostly before they come into flower, and during their growth—that is, from the time when they show their flower-buds until late in autumn—they require the best places in the greenhouse. If neglected only for a short time they are almost lost, and once in bad health it is difficult to restore them to their former luxuriance. They require the loving care of the grower at all times, whether resting or growing. For this reason *Amaryllis* will never become a florist's flower, but it is a most desirable plant for the amateur and window gardener, for the wealthy private flower lover, and for the greenhouses of parks and botanical gardens. In such institutions *Amaryllis* are indispensable and should be grown in unlimited quantities. Scarcely any other plant is so easily grown as these if their few requirements are understood. They need a season of rest in winter, when water must be entirely withheld, or only sparingly and judiciously applied. During their season of growth in spring and summer they need abundant moisture, being particularly benefited by water in which a small amount of superphosphate has been dissolved. Manure-water is also a good stimulant. I keep the more delicate hybrids in the greenhouse the year round, while the strong-growing kinds are planted out in open hot-beds late in May, and in October they are again potted and transferred to the greenhouse. I use a soil of equal parts of loam, old cow-manure and sand, to which crushed charcoal and old plaster or a little lime is added. As soon as the robust-growing kinds lose their leaves they are placed under the benches with no water at all until they show their flower-scapes late in January or in February, when they are watered a little and set in a warm, sunny place on the benches. When the scape has grown a few inches and the foliage appears, the plants are thoroughly watered about once in ten days. The more delicate sorts, as well as *Hippeastrum aulicum* and *H. reticulatum* and its progeny, must be carefully watered throughout the winter and the soil should never become dust-dry.

The finest named hybrids of *Amaryllis* will always be expensive plants, as they are exceedingly slow in multiplying. Empress of India has been in my possession ten years and I have only a stock of four plants. Fertilized with its own pollen it does not come true, the seedlings being less beautiful in form and color. Laurens Koster, Mozart, Conqueror, Leopoldii, Madonna, John Heal and others are now seven years under my care and I have not succeeded in obtaining one single offset. *Pardinum luteum*, Mrs. Burbidge and *Solandiflorum* conspicuum I have had for more than twelve years and they have not produced a single side bulb.

Most of the *Amaryllis* seen in cultivation are hybrids of *Hippeastrum vittatum*. Of this strain the late Mr. Souchet, of Fontainebleau, France, and especially Mr. Martin Hoffmann, of Berlin, introduced many striking hybrids. They often came into flower in two years from the seed. They are always characterized by narrow, pointed segments and mostly an overabundance of green in the tube, but they stand a good deal of rough handling among other greenhouse plants, and are therefore usually preferred by florists. But they cannot compare with the magnificent hybrids I have named.

Milwaukee, Wis.

H. Nehrling.

### The Hardy Plant Border.

**A** LONG the front row of the herbaceous border large patches of the Moss Pink, *Phlox subulata*, now make imposing masses of color. For a dry, sunny position this is an excellent plant, its evergreen prostrate stems providing a thick mat which completely hides the ground. Now the stems are quite hidden

from view with the profusion of blossoms. *Stellaria Holostea* is a good companion to the *Phloxes*. It is a plant that quickly spreads and needs frequent trimming to keep it within its allotted space. It has a low decumbent habit, and its flowers are produced in dichotomous cymes and measure about three-fourths of an inch in diameter. The drooping blue flowers of *Polemonium reptans* add a decided and distinct color to the edge of the mixed border where the white flowers of *Arabis alba* and *Stellaria* are abundant, and the pink tints of *Phlox subulata* and *P. procumbens*. This *Polemonium*, which is creeping in habit and has pinnate leaves, when in blossom is about eight or ten inches high. A good rich light soil suits it well, and it thrives here in a sunny position. *Erysimum pulchellum* is an exception to many of the weedy species of this genus and makes compact plants about a foot in height, with pretty sulphur-yellow flowers. It thrives in the rock garden and also does well in light rich soil in the front of the mixed border.

The summer Snowflake, *Leucojum æstivum*, is well worth a place in our gardens. The foliage of this bulbous plant resembles that of the *Narcissi*, and its dainty white Snowdrop-shaped flowers are borne in small drooping clusters on stout erect stems from fifteen to eighteen inches in height. The individual flower has six perianth segments, each delicately tipped with green. The plant is hardy here. Bulbs are procurable in the fall, and if planted then will blossom the following spring. It thrives in a light rich soil, and in Europe, from whence it came, it is frequently planted in the grass. *Muscari neglectum* has been grown here for a number of years as easily as the common Grape Hyacinth, *M. botryoides*, and a small bed is now attractive with its numerous racemes of deep blue flowers on scapes about nine inches in height. This south European plant flourishes here in light rich soil in an open position. The beautiful *Epimedium macranthum*, brought from Japan to Europe in 1836, grows about a foot high. Its leaves are biternate, and the white flowers are produced in short, close racemes. It is a good stock garden plant, and many of the *Epimediums* are useful under trees where herbaceous plants can be grown with only partial success. *Aquilegia Canadensis* is always graceful and pleasing and is as happy in the rock garden as when growing wild in rocky clefts on steep hillsides. The decumbent stems of *Euphorbia Myrsinites* make a graceful draping in the rock garden. When not in blossom this plant is pleasing for its distinct light green glaucous leaves, which make it noticeable even from a distance. This *Euphorbia* is now flourishing, and umbels of yellow flowers are borne at the ends of the stems. Although a native of southern Europe it is hardy here without any protection. The finest yellow flowers now seen out-of-doors are those of *Alyssum saxatile*. This plant, while desirable for use in borders, never gives the satisfaction it does when grown in the rock garden, where its stems are so disposed as to show off the dense masses of golden flowers to the best advantage. It enjoys a sunny position and the bright flowers are most beautiful in the sunlight. A few bulbs of *Tulipa Greigi* have been grown here in the same place without being disturbed for eight years. If planted where water will not lodge about the bulbs in winter they are perfectly hardy, and if not moved often they will flower each spring. *Tulipa sylvestris* is a species well worth growing. It soon naturalizes itself among the rocks and stones, and its showy, clear yellow flowers are refreshing and satisfying.

A choice and hardy plant for the rock garden is the beautiful *Hutchinsia alpina*. This neat, compact, dwarf plant has small shining leaves and pure white flowers, produced abundantly in clusters close above the foliage. An open position and a light soil in an elevated part of the rock garden seems to suit its needs. The hardy perennial, *Corydalis nobilis*, a Siberian plant, is pleasing when in flower, but has the fault of not increasing rapidly. The plant in bloom now is ten or twelve inches high, and its stems are thickly clothed with glaucous bipinnate leaves, the flowers produced in a dense cluster at the end of the stems. The flowers are of a rich golden yellow, with a small reddish chocolate mark in the centre. The creeping Forget-me-not, *Omphalodes verna*, grows luxuriantly to a height of six to eight inches under the shade of some Hemlock-trees. This charming plant bears handsome deep clear blue flowers with white throats, and its stems are clothed with deep green, ovate-cordate leaves. It increases by runners, and when once established soon covers a piece of ground.

On bright sunny days the object most admired by visitors to the Botanic Garden is a fine patch of *Anemone nemorosa*, var. *Robinsoniana*. This lovely plant does not open its flowers on dull days. The flowers are much larger than those of the

species and are of a delightful sky-blue color. Self-sown plants of the Iceland Poppy, *Papaver nudicaule*, are giving a plentiful crop of yellow cup-shaped flowers now. The flowers of the white variety harmonize well with the yellow ones when they are grown together.

Harvard Botanic Garden, Cambridge, Mass.

Robert Cameron.

### Seasonable Flower Notes.

MARGUERITES are indispensable among the flowers grown for cutting. Their cultivation is easy, constitution robust, and they are almost free from disease and insect pests. With proper treatment Marguerites may be kept in bloom the year round. Old plants which flowered during winter before last when turned into the garden furnished flowers all summer long, though they were rather small. Finer flowers are obtained from young plants, and for winter blooming a fresh lot is raised in the spring and grown on during summer in the garden. Growers of plants for market usually keep them in pots, as they do not lift well, and, besides, with unrestricted root-room they become too large. Marguerites form a conspicuous feature of the display with Azaleas under canvas at Mr. H. H. Hunnewell's place during late May and early June. The kind best suited for growing into bushes such as are used here is the glaucous-leaved type, with finely cut foliage and small flowers. In two or three years they make very large bushes. They are carefully trimmed after the display is over, plunged in pots in the garden and kept from blooming for the remainder of the season. They are gross feeders and respond to liberal treatment. Specimens grown solely for a spring display are kept in cool houses during winter until a few weeks before they are wanted in bloom.

For winter cutting we have found Halleri major the best white; it has large flowers with long stems. Usually we have cut the flowers off singly, but last winter we commenced cutting them in sprays, giving a foot or so of stem. When a plant had been cut over it seemed as if all the flowering shoots had been taken. We obtained just as many flowers in the long run, and could begin to cut again from where we started to cut in about ten days. Sprays with foliage can be used with better effect and last much longer. The unopened buds develop in water, and with a little trimming over we have kept flowers for two weeks.

We have a yellow variety known as Halleri, though it cannot be correctly named so, as it differs but slightly from Etoile d'Or. It is free, however, and that is a quality rare in yellow varieties, so far as my experience goes. During a recent visit to Denys Zirngiebel's establishment at Needham, Massachusetts, I saw a large number of Etoile d'Or blooming splendidly. This stock was imported from France recently, and it is claimed to be an improved type and superior to the variety generally grown in this country under that name. We shall be fortunate if we find it a free-blooming variety and of good constitution, as a yellow Marguerite is badly needed. I found the new giant Californian also in bloom. That the plant, at least, will be a giant, there is not much doubt. The flowers are larger, but the increase in size is rather in the disk than in the length of the ray-florets. It is just about the size and has the general appearance of our common field Daisy.

The double form of the annual *Chrysanthemum coronarium* has come to be known as the double Marguerite. But common names which carry a wrong impression should be avoided.

The popularity of the modern French Pansies, distinguished for their large size and gorgeous coloring, is due to the efforts of Mr. Zirngiebel, who is a specialist in these as well as Chinese Asters. His intimate acquaintance with Bugnot, the famous French raiser of the type which is known by his name, has enabled him to procure seeds of the very finest strains. He is always careful to tell the visitor that he paid \$80.00 for the first ounce of seed he bought of the popular Trimardeau. Finding it moderately hardy, he improved the opportunity to select the hardiest and best colors for perpetuating, and it is probable that Zirngiebel's Trimardeau is the type of all the "own" and "selected" stock now offered throughout the country. It was hardly to be expected that the tender and highly bred browns and reds so common in the genuine Bugnot strain could be merged with the Trimardeau. It has been done, and this season, to purple, white and yellow, will be added brown colors. The Pansy is now a profitable flower for florists.

The two new Hybrid Sweetbriars, named Lord and Lady Penzance, have stood well at Mr. H. S. Hunnewell's place in Natick. They are as hardy as our Prairie Rose. Syringa Ja-

ponica is showing well for bloom and promises to be earlier than last season. The specimen here has reached the dimensions of a small tree, and evidently a mature specimen will grow to be forty feet in height. Flowering Thornis, Plums, Apples, Quinces and Cherries are represented here in large numbers. A set, at least, is kept in one quarter of the garden for convenient study as well as effect. *Berberis Aquifolium* on a north-east slope is full of bloom, and with foliage of classic cut it makes an elegant bush. It will not stand bright sunshine in winter, as might be seen by one bush farther to the south being somewhat burned. A splendid patch of *Daphne Cneorum* is evidently suited on this north-east slope. It is seldom we find this handsome trailer free from winter-killed branches. The delicious odor from its lovely pink blossoms filled the air in its locality.

Wellesley, Mass.

T. D. Hatfield.

### Flower Garden Notes.

WITH a garden of flowers judiciously planted, there is no period more interesting than the present when all plants are coming on rapidly and many are at their best bloom. The mixed border of bulbs, perennials and annuals makes up the ideal combination that will give flowers from April until October, a result not to be gained in any other way, and at the same time it is the most economical way of filling a border, for few plants need replacing each year except the annuals, and the most of the labor lies in weeding out such as are encroaching on their near neighbors; there are always many of these, and a good time to see to it is the present. Seedlings are the most troublesome, perhaps, and these can easily be detected now before they gain vigor. Larkspurs and Phlox are particularly prone to reproduce themselves, and they are almost invariably inferior, and, unless they are really needed in the border, should be pulled up without hesitation. The newer race of single tree Pæonies have wintered well and seem reliably hardy. There were some that never took kindly to the new conditions last year, and these have died during the winter, but the remainder are well set with flower-buds which will in a few days open about the same time as *Pæonia tenuifolia*, *P. Wittmanniana* and *P. corallina*, all of which are early-flowering species and valuable at this time of year.

It is a matter of surprise to me each season that there are not more of the species of Tulip planted in gardens for permanent effect. Their beauty, hardiness and longevity are all beyond question and look well mixed. The Parrot varieties, the forms of *T. Gesneriana*, *T. elegans*, *T. cornuta*, *T. sylvestris* and many more, are all thriving better after a five years' residence than if they had been newly imported from Holland. It is true they have all been lifted twice and replanted, but this was necessary owing to the way the bulbs had increased; but, apart from this, no other attention has been given. Oriental Poppies are also planted through the Tulip bed, a large one, and these will flower in June. All are seedlings from the true blood-red form known as *Papaver bracteatum*, and we find it comes true from seeds when taken from isolated plants. The Poppies in their turn will die down soon after the Zinnias are set out between the Tulips, and we shall have good effects from these in late summer until frosts arrive. There are no annuals that are so satisfactory as the Zinnias taken in all respects. No insect pests devour them, the flowers are admirably adapted for house decoration when cut, and they are easily raised from seeds. To get the young plants started well, however, they should be planted out on a mild hot-bed from the seed boxes, such as are used for growing on early vegetables. It is difficult to get good strong plants by June if they are set out on a cold bottom.

The Narcissus season is about past now; only a few of the Poet's varieties remain to open, and these are naturalized in the orchard under Apple-trees, where the white starry flowers seem peculiarly suited. They thrive well here, too; better, indeed, than in the border under richer soil and cultivation. The more robust Trumpet varieties do not do as well in the grass; they enjoy more nourishment, and will give correspondingly better returns. If the crop of flowers has been poor this spring, it is a sure sign of deterioration, and will probably be caused by overcrowding of the bulbs; ours all had to be transplanted last fall, and had been left a year too long. We did not get the amount of flowers this spring that the bulbs ought to have produced, and those that were potted up for forcing did not flower well. Next fall, however, they will be in fine condition to lift for winter blooming, and ordinarily home-grown bulbs give much better returns than those grown in Holland, and they can be had in bloom earlier.

We have been much pleased with the Burbank Canna. It is

very similar to Austria, but has more substance, is dwarter, and seems to have broader foliage. We have had a good opportunity to compare them, as we had the two, with Italia, in bloom at the same time. The trio will make valuable plants for flowering in the greenhouse in pots or tubs, and there is no doubt a place for them, even if they are not adapted to outdoor culture, as with the Crozy race.

Another very pretty novelty of this season is the so-called yellow Soupert Rose Moselle. It is extremely double, with a pretty apricot-yellow centre. Now that it is well known what admirable bedding Roses the Soupert Roses make, the Moselle will be a decided gain for summer bedding. The Roses of this race bloom perpetually in the open ground until frost, and their hardiness is undoubted.

South Lancaster, Mass.

E. O. Orpet.

**Xanthoceras sorbifolia.**—This beautiful little tree is just now the pride of our grounds (see vol. vi., p. 285). It has an erect habit and is now ten feet in height, and so completely covered with bloom that scarcely any of its very handsome dark green pinnate foliage is visible except a green spray here and there to give relief from the dazzling beauty of the flowers. These are large, upright, five-petaled and bell-shaped, and they have the unusual quality of changing their appearance day by day. When they open they are white with greenish centres, and the lower ends of the petals are marked with veins of lemon-yellow. By about the second day the petals have spread apart, showing more plainly the green calyx, and the veins have deepened to brownish yellow. About the third day a still more singular change takes place. The yellow has become a beautiful shade of pink, the green ovary swells and becomes conspicuous, and by about the fourth day the flower has utterly changed its character, as the veins and lower end of each petal are now a deep and beautiful shade of red, an indescribable color, very rare in nature. Meanwhile the petals have continued to spread apart, showing between them the green divisions of the calyx, and these changes, together with the swelling of the now prominent ovary, give the flower a totally different appearance from that which it presented at the time of its opening. On the spray which I now hold in my hand all the changes I have described can be noted at the same time, as some of the lower blossoms, which are persistent, are about four days old, and those at the top have just expanded. The individual blossoms are on long foot-stalks, and these are each ornamented with three green ovate bracts where they join the parent branch. The *Xanthoceras* seems to be perfectly hardy, and deserves a choice and conspicuous place in the shrubbery where it can have room enough to develop without being crowded. It has a single stem and is more like a small tree than a shrub. It is said to attain to the height of fifteen feet in its native country. Here it seems to find congenial soil and grows rapidly.

### The Red Cedar.

To the Editor of GARDEN AND FOREST:

Sir,—I read your article of April 14th and that of "H. S. H.," of Wellesley, Massachusetts, in your issue of April 28th, recommending Red Cedar for more general ornamental planting, with interest. Three years ago I had arranged to transplant a number of young Red Cedars found in old pasture-fields in western Pennsylvania to one of our parks at Youngstown, but chanced to read Bulletin No. 92 of the North Carolina Agricultural Station, published in August, 1893, before doing so, and upon the representation of the author, Professor W. F. Massey, horticulturist of the above station, that Red Cedar caused apple rust, and that the best remedy for the rust was the destruction of all Red Cedars within a mile of Apple orchards, reluctantly abandoned the idea.

From page 86 of the above bulletin I quote as follows:

"Rust of the apple is one of the worst diseases this fruit suffers from throughout the southern states. It is especially bad in sections where the Red Cedar abounds. This disease is caused by a fungus which, unlike all other fungi parasitic on tree fruits, is bimorphic—that is it exists at different seasons in two very distinct forms and on different hosts. The form on the apple 'rust' is botanically known as *Roestelia pirata*. The other form affects the Red Cedar, producing the so-called 'Cedar apples,' and is botanically known as *Gymnosporangium macropus*. The apple form or 'rust' is the immature form of the Cedar form. The fungus appears to be

restricted to these two naturally widely separated genera of plants. Hence, if all the Red Cedars, *Juniperus Virginiana*, within a mile of an Apple orchard are destroyed, no mature forms or reproductive spores of the fungus can be formed, and no further infection of the orchard can occur. The destruction of all Red Cedars within a mile will, in most cases, prove a complete remedy for 'rust.' When winds are unusually strong the mature spores may be carried for over four miles, but ordinarily they will not be carried over one mile. But one or two Cedars, if overlooked, may breed spores enough to infect several orchards."

However desirable the Red Cedar may be for ornamental purposes, it ought not to be extensively used if detrimental to apple-culture.

Youngstown, Ohio.

Volney Rogers.

[This rust is more dangerous to Quinces than to Apples, and it seems to have been proved (see Bulletin 80, Cornell Experiment Station, page 627) that the spores from the Cedar apples can be carried by the wind eight miles, and that it may affect Quince-trees, Apple-trees or Hawthorns at that distance. Nevertheless, the disease is not so serious in our latitude but that it can be kept down by spraying with Bordeaux mixture. If we spray our fruit-trees for the scab fungus and other diseases as we should we shall not find the Red Cedar such an injury to orchards that we shall feel any desire to exterminate it. This matter was referred to Professor Bailey, who writes: "I do not feel as much alarm as I once did over bugs and fungi. I should not deliberately plant Red Cedars around a Quince orchard, but if I wanted Red Cedars on my grounds I should plant them without hesitation. Upon my own farm I am planting hundreds of Apple-trees, and there are many native Cedars standing about the place which I do not expect to destroy, although I shall do so if they become intolerable nuisances."

The New York Park Board is planting Red Cedars in Morningside Park. Of course, there are no orchards near enough to be in danger, but the Hawthorns and other trees of the Rose family may be injured by the fungus. Nevertheless, the time is coming when spraying for other fungi will be a general practice in park plantations as well as in orchards, and we have little fear from the Cedar apples. Indeed, it would not be a difficult matter to remove the galls as they appear upon the Cedar-trees. There is no doubt as to the fact that the Red Cedar is the propagating centre of a rust which in another form grows on members of the Rose family, but with our present knowledge of the means of keeping it in check we see no reason to abolish the Red Cedar either from parks or from private plantations.—Ed.]

John Evans.

To the Editor of GARDEN AND FOREST:

Sir,—Dr. Harshberger has done good service to the early history of botany in the appreciative notice of John Evans, one of Philadelphia's famous botanist-gardeners. He has not overdrawn the picture of this modest, amiable and useful enthusiast. It is just fifty years ago, this blooming month of May, since Robert Buist, then in the prime of his career as a nurseryman, invited me to take a ride with him to see "a wonderful collection of plants by a farmer, who was also an excellent botanist." He drove to Evans' garden. Like many young men, I was inclined to believe I knew a good deal. But I was amazed at the great store of knowledge gained on that day's trip. The reference by Dr. Harshberger to the sawdust reminds me particularly of the lesson learned as to the love of the Raspberry and Currant for rotten wood, which for the first time I saw there.

That he gathered everything from the gardens around Philadelphia that could be obtained, the following little circumstance will testify to: While showing us his garden treasures nothing could exceed his enthusiasm. No trouble seemed too great for him in showing us everything that he thought would interest us. Mr. Buist was silent after entering the carriage on our homeward drive. After a long while he suddenly exclaimed, "Thomas, many a dollar that man has paid me for rare plants for his garden, but never again will I take money from him. He can have anything he wants from my place after this, and he shall not be charged a cent for

it." The story shows alike the goodness of heart of two men, both enthusiastic lovers of trees and nature.

Besides Bartram, Marshall and Evans, Corson deserves a conspicuous place in the well-deserved tribute of Dr. Harshberger.

Germantown, Pa.

Thomas Meehan.

### Early Flowers.

To the Editor of GARDEN AND FOREST:

Sir,—In early April, GARDEN AND FOREST editorially intimated, very pleasantly, that those of us who insist on having early flowers in our gardens were braving the elements and courting pneumonia and sudden death, things not to be expected of the average owner of gardens. This scarcely represents either side of the case. The average gardener simply does not appreciate the fact that there are countless flowers of most exquisite beauty which flower early in the year, and that he very much misses his opportunities if he shortens his garden season several months. I mean by average gardeners here those who have some enthusiasm on the subject, not those hopeless people who in these early days of May are turning loose the jobbing gardener in their borders to destroy all living things and "tidy up." As for the growers of early flowers they have "lived through March" again, for, as a matter of fact, the work in such gardens was finished in the previous year and one had only to enjoy the results, and this does not lead to much exposure. It is not necessary to linger or dawdle over a flower to absorb its beauty. A glance is often enough to fill one's mind with a beautiful image and start one's imagination, and imagination is as useful to a gardener as a spade. And then the first awakening of plant life is a rare experience which we see only a few times in our short lives. The luxury of a garden to me does not consist in spacious plant-houses filled with tropical plants, or in the flowers more especially valuable for the market; these are only incidents of a complete garden which should primarily contain plants of all seasons growing in the freedom of nature. An ideal garden should, among other things, comprise a few low hills, with a ravine or two, and perhaps a brook. Shrubs one should always have, not only for the flowers, but for the shadows which they make. On these hills, with some shrubs, one could naturalize a host of dainty plants, worthy of the early year, which would tempt one to wander afield, and furnish always those surprises which add so much to the pleasures of gardening. In all but the point of view of the lover of flowers this is very impractical gardening, for many flowers would bloom unseen. Still, even then they would feed the imagination of the planter who could not, perhaps, enjoy sometimes the fruit of his labor at the moment. However, one does not require a large domain for gardening pleasures of this kind. The smallest garden may be so stocked, if one represses a desire for bigness and show, that one can daily discern something new, and often come across some lovely thing planted long since and forgotten in the absence of bloom. One learns in collecting plants not to expect everything to flower each year, and it is curious how many plants one accumulates which for one reason or another flower very infrequently or not at all. The great drawback to the cultivation of any but a conventional garden is the impossibility of securing intelligent help for those minor operations which one would prefer to pay for. Help is very expensive when it results in weeding out everything except familiar plants. The cultivation of dainty plants would not, of course, appeal to those who must hunt their pleasures with a fund.

Elizabeth, N. J.

J. N. Gerard.

### Flowers at the Farmers' Club.

To the Editor of GARDEN AND FOREST:

Sir,—At the monthly meeting of the Farmers' Club of the American Institute, held Tuesday, May 11th, at 111-115 West Thirty-eighth Street, this city, there was a large and varied exhibition of flowers of hardy herbaceous plants and shrubs. The general subject for discussion was Hardy and Native Plants, and Dr. N. L. Britton, Director of the New York Botanical Garden, gave bibliographical notes of Dodecatheon, together with illustrations and herbarium specimens. Other speakers were Mr. S. B. Parsons, Mr. Samuel Henshaw, Mr. Husted, Dr. Ward, Mr. C. L. Allen, Mr. Leonard Barron, editor *American Gardening*, and Mr. Holloway, who stated his successful experience with Japanese Maples in an exposed position on Long Island. Mr. A. Herrington made a plea for the natural expression of trees and shrubs, and against formal pruning and clipping. Dr. Hexamer, President of the club, spoke of the charm of the hardy plant garden in its variety,

and said this is the garden for the home and the family and children, rather than for neighbors, and that it is a living kindergarten and nature's own garden. Mr. John Lewis Childs, of Floral Park, New York, had an exhibit of seventy-six distinct kinds of flowers, including *Viburnum lantana*, *Daphne Cneorum*, Meehan's *Halesia*, *Spiræas*, *Polemonium cœruleum*, *Tritelia uniflora*, *Iberis Gibraltarica*, Jonquils, *Lychnis*, hybrid *Aquilegias*, *Irises*, *Erysimum pulchellum*, the red and yellow flowering Currants, with many of the Japanese flowering Apples and Plums. There were also several distinct strains in seventy-four vases, among which were *Azalea amœna*, *Elæagnus longipes*, *Kerria variegata*, thickly flowered *Cercis Japonica*, large clusters of the sweet-smelling yellow flowers of *Berberis Aquifolium*, *Sambucus pubescens* and *Berberis Sieboldii*, often called B. Hakodate; seven forms of Apples were included in this exhibit, the most showy being *Pyrus Parkmanni*, the more delicately colored *P. floribunda* and the large double *P. coronaria*. The only *Rhododendrons* shown were from G. J. Aitken, gardener to R. Cook, Esq., Bayonne, New Jersey. Mr. A. Herrington, gardener to H. McK. Twombly, Esq., Madison, New Jersey, had large sprays of *Cornus florida*, *Halesia*, Judas-tree, *Exochorda* and the red-flowering Dogwood.

Other exhibitors were William Turner, gardener to William Rockefeller, Esq., Tarrytown, New York; W. Anderson, gardener to J. M. Constable, Esq., Mamaroneck, New York, who sent three luxuriantly grown masses of white, pink and purple *Campanulas*; Mr. S. B. Husted, Blaauvelt, New York, had a showy exhibit in twelve vases; several of the brightest masses were foliage of Japanese Maples and the Japanese Judas-tree. A. Grierson, gardener to Hicks Arnold, Esq., Rye, New York, who, with *Iris lupina*, *I. cristata* and *I. Korolkowi*, showed many of the best *Narcissi*, *Trillium grandiflorum*, Summer Snowflakes and the yellow *Doronicum Plantagineum excelsum*, besides a showy mass of Iceland Poppies and choice Tulips in large variety. M. A. Muller, Oasis Nursery, Westbury, Long Island, and Messrs. Siebrecht & Son also had interesting displays. Branches of *Xanthoceras sorbifolia*, *Epimedium*, *Colchicum*, English Cowslips and Wallflowers, *Alyssum saxatile* and single and double *Pæonia tenuifolia* were all seen. Mr. W. A. Manda, South Orange, New Jersey, exhibited a specimen of *Lilium longiflorum* with variegated foliage, and Mr. Barron showed a vase of the dainty little Hoop-petticoat *Narcissus*, *N. bulbocodium*. Mrs. C. S. Valentine brought an interesting collection of hardy cultivated and wild flowers gathered within the town limits of Cranford, New Jersey, including seven species of native Violets, Bellworts, True Solomon's Seal, *Pedicularis Canadensis*, *Arabis bulbosa*, Naked Broom Rape, *Podophyllum peltatum* and Pansies wintered out-of-doors.

New York.

### Recent Publications.

*The Procession of the Flowers and Kindred Papers.* By Thomas Wentworth Higginson. New York: Longmans, Green & Co. 1897.

One always picks up a book with a title like this with some apprehension. Men who consider themselves endowed in a greater or less degree with what is called a "feeling for nature" are apt to feel that the great mass of their fellow beings are less fortunate in this respect and need to be instructed as to what is going on about them. It too often happens, therefore, that a writer with very little imagination, no sense of humor, and a habit of taking himself seriously, feels moved to describe in a prosaic fashion what he thinks he ought to see, with the depressing results which are seen in countless books and magazine articles. This little book, however, is not a collection of such commonplace essays as those to which we have made allusion. The author is a man of scholarship, taste and literary skill. He is an original observer, and without making any pretensions to being a naturalist he describes what he sees with accuracy, and not infrequently his thoughts rise to the realm of poetry. The sketch entitled *My Outdoor Study* is perhaps the best of the half-dozen which the book contains, and is thoroughly enjoyable from beginning to end.

### Notes.

The leaves on the young shoots of the Wild Cherry, which is found abundantly in the hedge-rows of every Long Island farm, are now so fully grown that branches for the decoration of fruit-stands are again in the market. The red stalks and midribs of the leaves, the rich color of the bark on the new growth, the delicate green of the glossy foliage growing lighter toward the tip of the branches, together with the grace of form and the silver-bronze tints of the half-grown leaves at the summit, make a singularly beautiful combination.

The permanent portion of the great Hamburg Exhibition is now about completed. The location is on undulating ground, and it will be decorated with thousands of plants of Azaleas, Rhododendrons and Roses, in bloom or in bud, with a great number of conifers, Hollies and other plants, grouped for effect. The first of the six special exhibitions began on the first of May, and the display was most imposing and extensive, filling all the available space in several buildings, the largest of which covers two acres of ground. The managers have expended half a million dollars on the buildings and grounds.

The prices of flowers were, perhaps, never so low in this city as they were last week, when carnations brought as little as \$1.00 a thousand, and a regular rate for roses was \$5.00 a thousand. Indeed, many of the highest-grade flowers could not be disposed of at any price. Besides the close of the social season, another reason for the slow sales is the abundant use of sprays of Lilac and other early spring flowers, both wild and cultivated, and flowering branches of trees and native shrubs for church and other decorations. These flowers are for sale by the armful on the street corners, or they can be had for the picking almost anywhere in the suburbs.

Professor Jordan, Director of the New York Experiment Station at Geneva, has concluded that many of the 25,000 persons on the list to whom his bulletins are mailed would be benefited by popular editions of those which consist largely of tables of figures and elaborate reasoning, or are expressed in the concise and technical language of science. These popular bulletins will be sent to the regular mailing-list, but the scientific or statistical bulletins will be mailed to any who desire to examine them. We have received four of these popular bulletins, which seem to have been admirably edited by Mr. Frank H. Hall, of the station staff. One of these is on Gooseberries, another on Spraying for the Plum and Cherry-leaf Spot, a third is on Alfalfa, and a fourth on The Ravages and Treatment of Cut-worms.

A correspondent of *The Country Gentleman* gives the information that the destructive San José scale which has been brought from California into eastern orchards, to the great alarm of fruit-growers, has met at last with a check in Florida. Professor P. H. Rolfs, of the Florida Experiment Station, discovered it in vast numbers at De Funiak, and in the course of his investigation he observed many dead scales on trees which had never been sprayed or treated in any way. He found that the mortality was due to a parasitic fungus which had attacked the scale and killed it. This morbid fungus is a native of Florida; it can be propagated artificially with ease in unlimited quantities and it can be applied with a spraying machine like other insecticides. If all this is true, Professor Rolfs' statement that the discovery of this fungus disease marks the beginning of a new era in the methods of fighting with this insect will readily be accepted.

*Viburnum lantanoides* was one of the many shrubs in flower at the Arnold Arboretum last week. The flat, Hydrangea-like corollas of the neutral flowers on the margins of the cymes are an inch or more in diameter, and appearing above the half-grown leaves are very effective. The plant is good at all seasons with its sturdy growth, its large leaves, its beautiful fruit, changing through coral-red to dark crimson or purple in autumn; it is really one of the most desirable shrubs or small trees in our North American flora. When grafted on *V. dentatum* it grows very well, but on its own roots it is not an easy plant to manage. Two other native shrubs of the north-eastern United States, which are rarely planted, were in bloom, namely, the Bush Honeysuckles, *Lonicera ciliata* and *L. coerulea*. The first one, which attains a height of five feet, has rather large, greenish yellow flowers, borne in pairs, which are succeeded by bright red berries. The second, a smaller plant, some two feet high, has pale yellow flowers and blue fruit. Both of these plants are easily cultivated and are desirable in any considerable collection of shrubs.

The Alligator, or Avocado, pear, which is quite frequently seen in the New York market, is now grown largely in Ma-

deira, where it was introduced thirty or forty years ago. According to a late English Foreign Office report, the tree attains a height of from twenty to thirty feet in Madeira, making a tall, slender growth, and having smooth, green, Laurel-like leaves. Three to five of the pear-shaped fruits grow in a cluster and become a dark purplish brown when ripe. The pulp, which is often called "vegetable butter," is found between the thin skin and the globular seed. This is generally eaten as a salad, being seasoned with pepper and lime-juice, which is said to bring out the peculiar nutty flavor which is much appreciated by those who have acquired a taste for it. Others eat it as a dessert fruit with sugar as they do melons. The fruit is in season from the middle of September until the end of February, and is mostly consumed at home, although a portion of the crop is sent to England and to Lisbon. It is easy to export, but since the taste for it, like the taste for many other tropical fruits, is an acquired one, shippers only export it when ordered. The trees are propagated from seed, and the plants do not bear fruit until they have attained the age of from five to seven years.

We have received two inquiries from correspondents about the damaged foliage of young Norway Maple-trees, and they send specimens which seem to be blackened and wilted as if they were affected by some fungus or insect. Of course, without further examination we are not able to give the cause of the trouble, but some notes in the annual report of the Hatch Experiment Station of Massachusetts, just issued, may be of interest. Last year many leaves of the Sugar Maple in a dry and crisp condition were sent to that station for investigation, and the same condition was observed in different varieties of the Japanese Maple growing on the college grounds at Amherst. The leaves were wilted only on the west side of the tree which was toward the prevailing wind upon the day when they were affected, and this peculiarity seemed to extend all over the state on the 18th of May last. The wilting of the leaves which occurred quite generally through Massachusetts was evidently due to excessive transpiration of water, when the supply at the root was limited. The phenomenon was interesting, as it occurred on apparently healthy trees under unusual conditions, which lasted but a few hours. It is well known that the agitation of the leaves of a plant greatly accelerates the process of transpiration just as low humidity and a high temperature do. These were the conditions upon the day in question. Before this the rainfall had been below the average, and there had been continued droughts during two preceding years. The supply of available water, therefore, was less than usual, and under a strong, dry, warm wind the leaves of a tree like the Maple, with a large surface, might be expected to become exhausted and wilt badly. When this wilting was not carried to excess the leaves recovered. When it went too far it resulted in the shriveling and death of the foliage. It ought to be remembered, too, that young leaves give off more water than older ones, and Maple leaves are transpiring their maximum quantity in May. The report goes on to say that if there had been plenty of water in the soil the high wind would probably not have caused wilting, or if the same conditions had occurred in August or September, when the foliage was mature, less wilting would have resulted. This spring there does not seem to be any great lack of water in the soil, and we do not know the precise day on which the wilting occurred nor the course of the winds. It is not improbable, however, that accelerated transpiration and lack of water-supply was the cause of the damage to the leaves reported by our correspondents.

John Saul, one of the oldest and most widely known nurserymen of the country, died at his residence in Washington on the 11th instant, at the age of seventy-four years. He was born in Lismore, Ireland, where he was trained as a gardener, and while still a young man took the management of a nursery in Bristol, England, after having lived for a time in the Isle of Wight. He emigrated to this country in 1851, and was associated with Andrew Jackson Downing in the planting of the Smithsonian grounds and other parks in Washington. In 1852 he established the business which he has conducted for forty-five years. Mr. Saul was an enthusiastic grower of Orchids, and he has furnished the best American gardens with many of their rarest and most valuable plants. He was Chairman of the Parking Commission of the District of Columbia, which during the last twenty-five years has done so much to beautify the capital of the nation with well-planted street trees. His attainments commanded the respect of the best horticulturists and pomologists of the country, and he was esteemed by all for the integrity, simplicity and purity of his life.

One Way to Make Parks Attractive.

AT a conspicuous point on a hillside in the Arnold Arboretum there is planted a broad stretch of Forsythias, and about three weeks ago, when these shrubs were all in bloom, every visitor was struck by the great stretch of bright yellow which shone like molten gold in the sunlight. The Forsythia is a common shrub, and the only remarkable feature in this spectacle was its unusual extent, and the lesson it conveyed to every beholder was that a thousand Forsythias massed together on an acre of ground will make a much more striking display than the same plants would if scattered along a walk or a driveway for a mile or more. One would tire of such a blaze of yellow if it remained all summer long, but it burns out before it grows wearisome, and when the flowers have fallen all too soon, we think with pleasure of the remarkable pageant until the year brings around the flowering season again. If any one raises the objection that there is something spectacular or theatrical in planting of this sort, we must answer, as we have done before, that no one complains of nature for spreading out hundreds of acres of Rhododendrons on the summit of Roan Mountain, and, indeed, when one looks over this foreground at the great landscape beyond he sees nothing inharmonious in the picture. We do not tire of Dogwood-blossoms extending, like snowdrifts, for miles along a wood border in the middle states, or of ten thousand Red-buds in bloom at the same season, but we realize that these great combinations can produce effects which are marvelous in their impressiveness, and which ought to be repeated, if possible, in our great rural or semi-rural parks.

Of course, it is easy enough to overdo the matter in providing what are known as special attractions for visitors to the park. Playgrounds for games of various sorts, provision for skating or music and for museums of animals or plants have been introduced into parks, but they are to be commended only so long as they are held in strict subordination to the design as an artistic whole. It must be remembered, too, that the general landscape ought never to be marred by anything which conflicts with its motive, and great masses of flowers are not to be used without caution and judgment. But the wild flowers of any region,

for example, might be planted along the wood borders and in the glades of any park in such a way that they would not detract from its general beauty and would increase the attractiveness of its details. Besides this, such planting would serve a distinct educational purpose to all who are inclined to study their local flora.

It is in a line with this view of the case that we have in former numbers of this journal suggested that the borders of small park openings should be composed of shrubs which flower at the same time of year, one meadow belted with shrubs which flower in early May, another one with those which flower a week or two later, and so on, so that there might be a series of gardens like a panorama showing their flowers one after the other, according to their season. In a large park system masses of a single shrub or tree could be used in sufficient abundance to be impressive when their flowers are open, and yet they might form so small a portion of an extensive view as not to interfere with the variety of the landscape when out of flower. Along one of the driveways of the Arnold Arboretum a hundred and twenty different varieties of the common Lilac are now in flower, and while such a collection has an educational value for all who care to study these plants, it has besides a beauty which can only be appreciated by those who have been privileged to see them. The material for such striking displays is almost endless, and it need not by any means be confined to flowers; trees conspicuous for the beauty of their foliage in spring or autumn could be grouped together, and every one who has seen a swamp in winter lighted by the scarlet berries of the Black Alder can readily understand how the bright-colored fruits of many shrubs can be massed impressively.

This general subject was suggested by the great number, variety and marvelous beauty of the so-called "flowering Apples," which were at their best a fortnight ago, and the spectacle which they presented again proved that they offer unequaled material for massing in large places. A double-flowering Peach, especially the one with scarlet flowers, is almost a startling object when in full bloom. There is also a double pink form with flowers almost identical in color with those of our ordinary Peach, and a white-flowered form which cannot be excelled for the purity of its color and the profuseness of its bloom. These trees, however, have no great beauty except during their brief flowering season, and in our northern states, even when the buds are not killed by early frost, they are subject to many diseases and the attacks of borers, and are short-lived trees at the best. The Plums, too, of various species are delightful small trees, but the Apples as a class are altogether superior for general purposes. Most of them have no off-years and are covered with flowers every May. They are perfectly hardy and long-lived. The flowers on the various trees differ much in color and in abundance, some of them completely covering the branches, and others, although borne in great quantities, are sufficiently scattered to show the softening effect of the light green of the young leaves. The plants vary greatly in size. Some of them are low, spreading shrubs, others are small, bushy trees, others have an upright habit, and many of them have a way of throwing out long wand-like branches at graceful angles, which gives them an exceedingly picturesque outline. The fruit of some of them, especially the varieties of the Asiatic *Pyrus baccata*, is beautiful and fragrant. There are several species like *P. spectabilis*, *P. Toringo*, and perhaps others which have been frequently crossed, so that it is hard to distinguish some of the plants botanically, but they are all beautiful objects at any season, and especially so when in flower. The so-called Japanese Crabs are particularly showy on account of the color of their buds, which are crimson, and the white or pink masses of their flowers are often beautifully varied by a few unopened buds near the ends of the branches. Our own native Crab, *P. coronaria*, is also extremely useful for its large fragrant flowers and its odorous fruit, and it has the advantage of flowering later than those of the other

so-called ornamental Apples. Altogether, wherever it is desirable to add to the general attractions of a park a special display of flowers in early May, no class of plants can produce such splendid effects as these flowering Apples.

DURING the last session of the legislature of New Jersey a bill was introduced for the establishment of a commission to investigate the forests of the state, to determine the best methods of forest management adapted to existing conditions, to arouse general interest throughout the state in various ways, and to prevent, so far as possible, the ravages of forest fires. All these objects are worthy ones, but fortunately investigations have already been undertaken under the direction of the Geological Survey which look toward the accomplishment of the same ends. The forest interests of the state, therefore, will receive no injury because the Governor has failed to approve this bill. The State Geologist is qualified to superintend work of this sort, and everything which can be accomplished by this commission can be done by that officer. There is no doubt that the forests of New Jersey have a high value, but if the state makes any appropriation for protecting and developing this great natural resource, it can be used for the present to much greater advantage by the Geological Survey, which is already organized and active, than by the creation of another new board for this special duty.

#### The Source of Abietene.

ABIETENE is the volatile product from the resin of some west American Pines, and is the counterpart of turpentine which is distilled from the resin of some other Pines, chiefly those in the southern United States. Abietene is a more volatile liquid than turpentine, but both are hydrocarbons, although belonging to different series. About the year 1878 samples of abietene were received in Philadelphia with the statement in one case that it was the product of *Pinus Sabiniana*, and in another case that it was derived from *P. ponderosa*. Of recent years it has come to be understood that the commercial source of abietene is *P. Jeffreyi*. As I had in my possession the barks from *P. ponderosa* and *P. Sabiniana*, it occurred to me that something might be learned by examining the volatile product of these two samples. They were accordingly distilled, and, while the yield was small, it was enough to get the characteristic orange odor of abietene in both cases. In another experiment the amount of volatile oil in the bark of *P. ponderosa* was determined to be about 0.2 per cent. The bark, therefore, would not be a profitable source of the oil. It is probable that both *P. ponderosa* and *P. Sabiniana* have yielded samples of this oil, although it may be possible that *P. Jeffreyi* is at present the commercial source. Some years ago Professor Wentzell, of San Francisco, detected oil of turpentine in the resin of *P. ponderosa*. It is possible that both oils occur in different parts of the tree. Unfortunately, the commercial production of abietene and its resin is in the hands of a medicine company, which is disposed to attribute to these products curative virtues they do not possess. It is doubtful if abietene has any medicinal virtues superior to common oil of turpentine, or if the residual resin is superior to common rosin.

College of Pharmacy, Philadelphia.

Henry Trimble.

A river with its waterfalls and meadows, a lake, a hill, a cliff, a forest, ancient trees standing singly—it is objects like these which give beauty to a township and have a high use which dollars and cents never represent. They do more for education than hired teachers or preachers, and if the inhabitants of a town were wise they would cherish and preserve them. . . . I know a town in Massachusetts with a noble oak wood, to which, if preserved a century more, men would make pilgrimages from all parts of the country. As in many countries precious metals belong to the Crown, so here more precious objects of rarer beauty, like groves and river banks and mountain peaks, should belong to the public.—*Thoreau*.

#### *Quercus lobata* at Ukiah, California.

THE great White Oaks make the most delightful features of our valley landscapes. A few years ago, Ukiah Valley, viewed from the foot-hills, appeared to be covered entirely with one vast Oak forest. Throughout our rich bottom-lands immense spreading trees could be seen on every hand, now thickly dotting the grain-fields, now in extensive groves, and every valley view had a background of great white trunks and domes of foliage. The trees followed the smaller streams up into the foot-hills, they luxuriated in the deep rich coves about the base of the mountains, and even on the mountain slopes they grew wherever they could find the deep rich soil which seems essential to their happiness. Higher up the flanks of the mountain they soon gave place to the Black Oak, *Quercus Californica*, and the Post Oak, *Q. Douglasii*, which continued over the drier lands and over the mountains. But it was in the deep rich deposits of black gravel on the main valley floor that they grew most thickly and attained their greatest size. Year after year their numbers have been thinned slowly when grain or hay was the usual crop, but more swiftly since large orchards have been planted, and fruit, Hops and Alfalfa have become staples. But, in spite of the great gaps made in their ranks after all these years of cutting, thousands of veteran specimens still live and many large fields remain really groves

Fig. 25.—*Quercus lobata* in the Ukiah Valley, California.

of magnificent Oaks, which stand as they stood when the first white man entered the valley.

On the east side of the valley there was a wide belt a mile across and five miles long, which was once one great forest, and portions of it still contain our noblest trees. Other valleys in California have laid claim to pre-eminence in the beauty of their groves, and there are magnificent trees scattered through all of our valleys, but I believe that, taking into account the splendid proportions of some individual Oaks, the average size of all, with their

general stateliness and dignity of form and expression, the Ukiah Valley Oaks are unrivaled. Our valley is surrounded by high mountains, and is thus sheltered from the winds, so that the trees are apt to be symmetrical. The large rainfall and rich soil have done the rest.

Perhaps the most striking feature of the White Oaks, aside from their size, is the gray moss hanging in long streamers from every small limb. In the winter, when the moss is green on the large limbs, the contrast of this color with the pendent masses of gray moss and the brown bark is very beautiful. The types of White Oak are innumerable, and every tree seems to have a distinct form. There are full-headed trees, the top breaking into a wilderness of small ascending branches, and as fully furnished as if they had been pinched and trained by a gardener. Again we note immense boles with sturdy ascending branches, each large enough for a tree, and ending in stiff short branchlets. Then there are noble trees which branch evenly outward in perfect balance with hardly a twig broken and towering to 120 and even 140 feet in the air. Perhaps the most beautiful of all is the so-called Weeping form, in which the tree branches regularly and spreads widely, while numberless branches are thrown straight down. Some of these pendent branches are thirty feet long and little larger than a man's arm.

In a field on the east side of the river I recently measured some trees which ranged from eighteen to twenty-two feet in circumference at five feet from the ground. In the same field of about sixty acres there stood at least fifty trees over fifteen feet in circumference. Many of them had a great spread of branches, and one I measured covered a circle 144 feet in diameter. This tree girthed nineteen feet six inches, and its height was about 120 feet. Still larger specimens were to be found in another grove near by which has hardly been touched by the axe. In it I found a perfectly developed specimen in full health and not disfigured by the loss of any limbs. The trunk girthed eighteen and three-quarter feet at five feet from the ground, and it was more than 120 feet high (see fig. 25, page 202). The largest Oak that I have yet measured is growing here. The trunk has a small hollow on one side (see fig. 26, page 205), but otherwise it is sound. At five feet up it measures twenty-three feet nine inches in circumference, and at one foot above the ground 132 feet.

## Foreign Correspondence.

### London Letter.

**RICHARDIAS.**—The new yellow-spathed species, *Pentlandii* and *Elliotiana*, have lately been conspicuous in good collections and at exhibitions. Nurserymen are fully alive to the value of these two plants and are working up large stocks of them as rapidly as possible. They ripen seeds freely and they are also prolific in the development of supplementary buds on the tubers, which are a ready means of multiplication. I lately saw about a thousand healthy young plants of *R. Pentlandii* in a nursery in the south, and in one of our London nurseries I was asked three guineas for a plant of this species in flower. The spathes vary in size according to the strength of the plant and the cultivation. I have seen this year spathes of both species as large as the largest *R. Africana* (*Ethiopica*) and of the richest yolk-of-egg yellow. The two differ in that the leaves of *R. Elliotiana* are spotted with white and the spathe is uniformly yellow, while in *R. Pentlandii* the leaves are unspotted and the spathe has a large blotch of black-purple at the base inside. We have now, however, plants which combine the spotted leaf with the purple-blotched spathe; possibly these are hybrids between the two. There are also forms of *R. Pentlandii* with spathes of a sulphur-yellow color. The hybridist also has been at work on these plants, crosses between them and *R. Africana* having been successfully made. In my opinion these yellow *Richardias* are the most valuable additions that have been made to green-

house plants in the last twenty years. The time will come, and shortly, too, when the flowers will be offered by the dozen by the market-growers, and they will be as conspicuous in floral decorations as the White Lily of the Nile is now. Cultivators should bear in mind the fact that both *R. Elliotiana* and *R. Pentlandii* are warm-house plants.

**HYBRID RHODODENDRONS.**—The most beautiful *Rhododendrons* in flower at Kew at the present time are first hybrids—that is, crosses between two distinct species—and probably the handsomest ever raised is one called *Kewense*. This is the offspring of *R. Aucklandii* and *R. Hookeri*, both tender Himalayan species, and yet the progeny is as hardy as *R. Catawbiense*; at any rate, it is perfectly hardy at Kew. Even when not in flower it is a handsome evergreen, but when laden with its large loose trusses of big bell-shaped blush-white fragrant flowers it is a magnificent picture. It was raised at Kew and flowered for the first time about ten years ago. Grown in a cold greenhouse it is equally meritorious. The hybrids between *R. Fortunei* and *R. Thomsoni* are also flowering beautifully now. These were raised by Mr. Luscombe about twenty years ago, and he presented a set of them to Kew before they flowered. They have since been named *R. Luscombei*, Mrs. T. Dyer and Frances T. Dyer. Mr. George Paul, of Cheshunt, has raised a number of hybrids between *R. Fortunei* and some of the popular varieties of the *Catawbiense* type. These hybrids are also flowering at Kew, and in distinctness and beauty they prove to be of quite exceptional merit. Much has been done with the *Rhododendron*, but a great deal more remains to be done before we have got to the limit of the capabilities of this great and varied genus. A new and beautiful hardy species from China is now flowering for the first time at Kew, and we have seeds sown of several very remarkable species recently discovered in New Guinea. The potentialities of the *Rhododendron* as a garden plant are seen in the place it fills among hardy shrubs, among greenhouse plants and among perpetual-flowering shrubs for the warm house. These last we owe to Messrs. Veitch's operations upon the Malayan species.

**PALMS.**—If a census could be taken of the plants grown by nurserymen for indoor decoration it would probably show that Palms are first, and the rest nowhere. This is a very radical change from the state of things a generation back, when Palms, with the exception of *Livistona Chinensis* (*Latania Borbonica*), were grown only by admirers of the curious and rare. At that time the *Kentias*, from Lord Howe's Island, were rarities, and *Cocos Weddelliana* was as expensive as *Phalænopsis*. Now, millions of young plants of these two genera alone are raised almost every year from seeds. "Good Palms will sell when nothing else will," say the nurserymen. This preference for Palms is deplorable in one sense; it is driving many interesting plants out of cultivation. The nurseryman will not grow the collection plants which formerly were in favor; on the contrary, he is glad to get rid of them, often burning them by the houseful to make room for Palms. Surely we may yet hope that a taste for interesting and choice indoor plants similar to that which stimulates the collector and cultivator of Orchids, alpine plants and hardy trees and shrubs will not be allowed to die out entirely. Indoor gardening needs reforming and bringing into harmony with the best style of outdoor gardening. This can be done by discarding, as far as possible, the flower-pot and plant-stage and making the houses look less artificial than they are now. I am certain that the present style of greenhouse gardening is responsible for the lack of interest in it which is so evident in the horticulture of to-day. Two of the best proofs of this are in the preference visitors to Kew have for the temperate house, where the plants are all grown naturally in beds, and in the popularity of two show-houses in the nursery of Messrs. Veitch & Sons at Chelsea, one for Orchids and the other for greenhouse plants. In these there are no stages, the plants standing in natural groups in artistically arranged cork, rockwork and cushions of *Selaginella*, etc.

NEW PLANTS.—The following have recently received certificates: *Rhododendron superbissimum*; a hybrid between *R. Veitchii* and possibly *R. Edgeworthii*. These are the parents of *R. Forsterianum*, one of the best of greenhouse *Rhododendrons*, but Messrs. Veitch's new hybrid differs from this in the form of its leaves and in the size of the flowers; which are broadly campanulate, wavy and nearly six inches across. *Lomaria ciliata grandis*; a form with very wide pinnae, approaching in this respect *Blechnum spiliense*. It was shown by the raiser, Mr. May, of Tottenham. *Lithospermum tinctorium*; a pretty alpine with the habit of the common Bugloss, but smaller in all its parts. The flowers are in terminal clusters and are of a deep blue color. It is a native of Arabia and Egypt. According to botanists, its correct name is *Arnebia tinctoria*. It was exhibited by Mr. Bennett Poë, of Cheshunt. *Primula Trailli*; an Indian species very closely allied to *P. involucrata* (Munroi), differing only in having larger leaves and flowers. The former are elliptic, about four inches long, green, with long petioles, and the flowers are in loose clusters of about six on long slender scapes; they are nearly an inch across, milk-white and fragrant. Shown by Mr. G. F. Wilson, Weybridge. *Narcissus Naiad*; a hybrid between *N. Empress* and *N. triandrus*, and one of the best of the hybrids raised by Mr. Engleheart. It has large white segments and a large wide-spreading straw-colored trumpet, and is a most distinct plant in every way. It was awarded the prize for the best new seedling *Narcissus* of the year. *Odontoglossum crispum heliotropium*; a first-class certificate was awarded to a plant shown under this name by Mr. R. B. White, Arddarrock. The flowers are large, white, tinted with rose, and heavily blotched with red-brown spots. It is one of the most beautiful of the many forms of this Orchid now known.

London.

W. Watson.

## Plant Notes.

### *Pyrus Japonica*.

THE Japanese Quince, *Pyrus Japonica*, also known in catalogues under the name of *Cydonia Japonica*, when well grown is one of the most satisfactory of the early-flowering shrubs which have been brought to our gardens from those of Japan or China. Among the points which recommend it to popular favor are its hardiness, quick growth, early flowering, its bright, clear-colored blossoms and its clean and not often diseased foliage. To these qualities might be added its ready adaptability as a good hedge plant, and the fact that some use may be made of its bright greenish-yellow fruit in the autumn.

Although accounted a hardy shrub and one which will bear a temperature passing to some degrees below zero of Fahrenheit, it will be sometimes injured in winter if grown in too cold and too poorly drained soil. For this reason it should be planted in a warm, well-drained soil, such as a sloping bank. Here the wood and buds are most likely to be thoroughly matured in the autumn before frosts occur.

The original type of this Japanese Quince appears to be the single deep scarlet-flowered plant which represents the species in most gardens where it is grown. A white-flowering variety is now frequently seen in gardens, although it cannot be called common. This white-flowering variety is found in catalogues under the names of *simplex alba* and *nivalis*, although a third one is offered under the name of *Pyrus Japonica candida*. The first two are much alike or identical, the third has rather broader, larger leaves and larger flowers with large rounded petals. One of the prettiest of the varieties is intermediate in color, between the red type and its white variety. This appears to pass under two or more names, *Moerlosi* and *Rosea* being most common. The buds of this are light rose-colored or pink; when the flowers open they are white and rose-colored, often curiously blotched, and as the blossoms grow old they often change to a deep dull red before the petals fall. The plant sold under the name of *Versicolor* has very simi-

lar characteristics, but varies enough to show that it had a separate origin. The variety known in some collections as *Grandiflora* has flowers larger than normal, at first pale or whitish, tinged with rose color, the rose color gradually diffusing through the petals and changing them from white to red as the blossoms grow old. The form *Aurantiaca* has what are called orange-scarlet flowers, a variation such as may be found among a number of seedlings.

A variegated-leaved form, called *Tricolor*, is interesting to those who care for the abnormal in nature. There are several so-called double-flowering variations, but the "doubling" is not far advanced, and a few only of the stamens have been changed into petals in addition to the normal number of five found in the flower.

*Pyrus Maulei*, or *Cydonia Maulei*, a comparatively recent introduction into our gardens, is considered a distinct species by some botanists, and by others merely a distinct variety of the Japanese Quince. It is a smaller and dwarfer shrub than the better-known Japanese Quince, and has smaller leaves, flowers and fruit. The flowers, however, are of a very bright rich red color, and the plant is really a great addition to our list of hardy shrubs. The fruit is bright yellow when ripe and strongly fragrant.

The fruit of the Japan Quince varies greatly in size and appearance on different forms, and it is generally regarded as worthless. With care, however, and in combination with some other fruits, it may be converted into a very agreeably flavored jelly, so that the plant may be made to furnish good material for culinary purposes as well as being ornamental. It makes a most satisfactory hedge in many situations.

For all ordinary purposes, as for hedges, where the red-flowered type is desired, it is sufficient to grow from seed, but any of the so-called varieties or any improved variation from seed should be grown from layers or cuttings. Grafting is often practiced, but shoots from scion and stock too often grow up together and become intermixed in the bush, the stock usually being the stronger and supplanting the scion.

Arnold Arboretum.

J. G. Jack.

### *Erythronium giganteum* and *E. Hendersonii*.

THE best-known Pacific coast Dog's-tooth Violet is *Erythronium giganteum*, although it has been distributed under the incorrect name of *E. grandiflorum*. All of the bulbs of *E. grandiflorum* offered to the public for many years past by American seedsmen were really *E. giganteum*. This is the tallest and most floriferous of all Dog's-tooth Violets. While under ordinary conditions from one to five flowers are usual, it will, under favorable conditions, produce from eight to as many as sixteen straw-colored revolute flowers of large size, no larger, however, than are produced by other Pacific coast species. It grows on the coast ranges on the Pacific slope from San Francisco Bay to southern Oregon. It is not found in the heavily timbered belt which runs parallel with the coast line, but from that section to the great valleys toward the east it is common. On northerly slopes in timber in a loose soil it is at its best, especially where mold has gathered in rocky ledges. Few more beautiful floral displays can be found than the large beds of these in their full bloom. In places they are so thick that their leaves cover the ground and the slopes are yellow with their flowers. In the garden they come on after *E. Hartwegii*, *E. Hendersonii* and most of the *E. grandiflorum* varieties are gone. Plants of the *E. revolutum* type follow them in flower and outlast them, and, in fact, form seed-capsules before *E. montanum* shows in flower.

*Erythronium Hendersonii* is a beautiful species from southern Oregon, which, although differing a little in form from *E. giganteum*, has a similar leaf and revolute flower. Its color is a fine shade of pink-purple, with the centre a very deep purple to almost black. It is altogether a charming flower and comes third in the season's succession.

## Cultural Department.

### The Vegetable Garden.

**C**OPIOUS rains during the middle of May and the absence of unseasonable warm weather and of frosty nights have been specially favorable for starting vegetables of nearly all kinds. Peas especially revel in such weather and have made stout haulm which ought to yield good returns later. Our hot summers make it impossible to produce as large, sweet, and luscious peas here as in Great Britain, where the cooler, milder climate is extremely favorable to their growth, and their bearing season is much longer. With a little extra attention, however, a satisfactory crop may be grown. Hot weather forces the vines unnaturally, and if the roots are dry one good picking of peas is about all the vines will yield, when the ground might as well be cleared for another crop. A mulching between the rows with Meadow Grass or similar material is useful. If the Peas are sown where they can be watered artificially, and a good standing sprinkler is kept running night and day in the patch, the yield will be increased immensely. For a late crop we still find the old Champion of England indispensable. There are many varieties which produce larger pods and peas and as heavy crops in England, but they are not so satisfactory here for some reason. Stratagem, Yorkshire Hero, Shropshire Hero and Duke of Albany do fairly well; other kinds are unsatisfactory.

Lima Beans should be sown here about the end of May when the weather is settled and warm. If they are sown earlier they do not germinate satisfactorily. We find Burpee's Bush Lima the best of its class and have discarded the Pole Limas entirely. There is really no use for them when the bush varieties will yield fully as fine pods and many more of them in proportion to the space occupied, without the labor of erecting poles and keeping the vines fastened to them in the earlier stages of their growth, and the probability of their being blown down by autumnal gales. We make fortnightly sowings of String Beans until early in August, so as to have a constant supply.

Peppers and Eggplants do best in very rich soil. If a regular supply of liquid-manure and a light mulching can be afforded to the Eggplants the fruit will be greatly improved in quality as well as in quantity. Potato bugs are likely to be troublesome during the early stages of growth, and the plants will need hand-picking daily. Neglect in this particular may mean the loss of every plant in an incredibly short space of time. To destroy the same pests on Potatoes we mix one pound of Paris green with two bushels of air-slacked lime, and dust this over the plants with a fine sifter in the early morning while the foliage is damp. Two applications during a season are sufficient to keep them under.

Tomatoes have recently been planted out. These we will look over once a week to tie up and do necessary thinning out of laterals. Tomatoes are now generally trained on poles or to trellises, and those who have once tried this system will hardly care to see their plants rambling over the ground as in former years. For the best success Tomatoes should be planted on different ground at least every second year. The trellises are easily moved if they are light. Aristocrat and Autocrat are two useful dwarf-growing Tomatoes of the Champion type specially adapted for gardens where space is limited. We have tried both for forcing, but they were not a success. Generally we pick our first fruit out-of-doors about the end of June, from plants set out from six-inch pots with fruit already set. Our indoor plants provide a good supply until the middle of July, when we throw them away. A batch which commenced to fruit at the end of February is still bearing freely, and the fruit of a later lot is just beginning to ripen. As our plants are all grown in pots frequent waterings and copious doses of strong stimulants are needed at this season. Of varieties we have forced this season Cornet is satisfactory; the fruit is of medium size, firm and of good flavor, and it sets very freely in winter. Eclipse has done extremely well. We picked an average of sixty-two fruits from twenty plants in one batch. The fruit is not quite so firm as that of Cornet, and if planted out a large proportion is liable to come hollow. May's Favorite and Comrade are both desirable sorts to fruit from January onward. Some of our most popular outdoor sorts are failures under glass. At a commercial place near-by a grower who had not handled Tomatoes before planted a house 100 by 20 feet with Acme, Lorillard and Perfection in December. A house of this size planted with the proper forcing varieties and treated properly should have yielded 4,000 pounds of fruit, whereas not a bushel has been picked thus far, while the house is a wilderness of laterals almost as dense as an African jungle.

Many growers now transplant their Onions instead of sowing them outdoors, and this is certainly the best method. Plants set out about April 15th are now growing vigorously, and all the attention they will need from now onward is to stir the soil with a hoe or cultivator, and a good watering in dry weather, to make a crop of extra-large bulbs. Doses of liquid manure, applied once in ten days after the middle of June, particularly after a rainfall, will greatly increase their size. Onions are among the few crops which succeed on the same ground year after year. If Leeks have not yet been sown there is still time to make a sowing. To produce good Leeks they should be liberally treated during the growing season, like Celery. Musselburgh and The Lyon are first-class sorts. Early Parsley kept in frames over winter is now running to seed. This is a suitable time to make a sowing of Parsley for plants to be lifted in the fall and set in frames or placed in a cool greenhouse. When large enough to handle, the plants should be thinned out a foot apart. A variety of sweet herbs and pot herbs are needed on most private establishments. Some of these are annuals, while many are perennials. A sowing of any of these may now be made. Sowings of Cauliflower made now will give a good supply of heads in the fall. Brussels Sprouts, one of the finest of the Brassica family, may still be sown, while Savoys, Curled Borecole of different sorts, and Cabbage should not be neglected. Lettuce should now have as cool and moist a location as possible, and a fortnightly sowing will assure a constant supply. Good summer kinds we have tried are Deacon, Black-seeded Tennis-ball, Salamander, Big Boston and Sutton's Cabbage.

Early Celery has recently been planted outdoors in well-enriched trenches, and will be kept moist at the root to insure its steady growth. Our main sowing for winter use is not quite large enough to prick out yet. An additional sowing of Paris Golden should be made now to come in during October and November; if this is sown now there is less danger of its rusting. Cucumbers in frames and houses, particularly those of the English type, now require an abundance of water and frequent doses of manure, while a syringing with tobacco-water or some other liquid insecticide will keep black fly in check. Unless fumigation is done lightly and carefully it is liable to scorch the foliage badly. Squash bugs will shortly be about in swarms, and they will speedily destroy all vestiges of Squash, Cucumber and Melon plants if they are not attended to promptly. Some of these details are liable to be neglected during the rush of bedding out in the flower garden. We dust our plants with tobacco-dust and lime, particularly on the under sides of the leaves while the foliage is damp. A daily journey should be made among the plants so that proper care may be given them, and a few hours of neglect may cause serious loss.

Taunton, Mass.

W. N. Craig.

### Notes on Garden Irises.

**B**EFORE the Irises mentioned on page 188 have ceased to flower the bolder-bearded species and varieties will make their appearance. As usual, the first to bloom is the purple-flowered *I. Germanica*, which is the most universally known species of the family. In fact, non-gardening people if interrogated will always say that "an Iris is a big purple flower often seen in old gardens." Following the type closely is the white variety and also the white Florentine Iris. Both of these Irises are slightly tinged with light purple, but are strikingly beautiful, having also bold flowers on tall stems and broad erect leaves. Both of these species are scentless. The flower which often does duty as *I. Florentina*, and is fragrant, is a form of *I. pallida*. There is a pure white form of *I. Florentina* known as *I. albicans*. Good forms of this are treasures not often to be had from the dealers.

Lately there has been introduced a superior form of *Iris Germanica*, variously known as *Macrantha* or *Amazon*. It bears a flower much larger than the type, but similar in coloring. The hybrid German Irises are also coming into flower. Of these I have several times in GARDEN AND FOREST given details which it seems unnecessary to repeat, but it may be said again that a carefully selected lot of these plants will give at this season in the garden of hardy plants a most charming and delightful effect with a minimum of trouble and expense.

Of a distinct type are the Siberian Irises, which are also of this season. These are beardless Irises with tall grass-like leaves, and as they have short creeping underground rhizomes they make dense clumps of the utmost hardiness, and are very useful and effective in the garden. There are several forms with purple and white flowers which are of moderate size. There is also another narrow-leaved Iris, very common through Asia, *I. ensata*. The tall leaves are strongly veined, and the

flowers, which have narrow petals, light lilac in color, are borne on short stems among the leaves. I rather enjoy this species, despite its tendency to weediness, but as no one else seems to fancy it, it is, perhaps, better not to recommend it.

It is very difficult, perhaps impossible, to convey to the reader correct impressions of the colors of Irises as so many of them are purple. As this is a compound color, ranging from the reds to the blues, it has innumerable hues which one can only hint at as they appear in the various flowers. Not all of these hues are pleasing to me, and perhaps others might not fancy forms which might be commended, but I have no hesitation in noting the beauty of *I. Kochii*, which is of a most intense purple color of a reddish tint. This bears large flowers, and is among the most desirable of garden Irises.

None of these Irises offer the slightest difficulty in cultivation in ordinary garden borders, the intention of these notes being to indicate only the useful, easily grown and effective kinds. This note, it will be observed, mentions two types of Irises, those with thick rhizomes which creep at or near the surface, and those with thin underground rhizomes—*I. Sibirica* and *I. ensata*. The latter may be planted, like any herbaceous plants, with the crowns at the surface. The others should be planted with the thick rhizomes only half-buried. These may be planted at any time when the ground is warm, but I prefer, if possible, to move them just after flowering, as they soon thereafter make a new growth, and by autumn are strongly established and will be effective the next spring, which they seldom will be if planted in the fall. The exception to this would be when plants are only moved a short distance and are not checked. In such cases it really is of little importance if planting is deferred to that time. Ordinarily, however, one receives the plants from a distance, and they have become dormant. In such cases, if received in the late year, I prefer to winter them in frames.

Iris notes for the middle of May would not be complete without calling attention to some other species which are by no means to be considered as reliable garden plants. At this time commence to flower those curious Asiatic Irises which, being natives of countries with rainless summers, require special and careful culture. They are to be classed among those which the gardener considers "interesting" plants, by which is usually understood those which give more trouble than flowers. *Regelia* and *Oncocyclis* Irises are, however, amenable to rational treatment, which will vary somewhat according to latitude of the garden. Here where we have very severe weather sometimes and only occasional snow for protection, it is necessary to retard the growth of the foliage till early spring, say April. By planting the roots, about four inches deep, at the end of November, the leaves appear above ground after hard frosts have ended. They are planted out in fully exposed borders and care is taken that they are well supplied with water while growing. Soon after flowering the old leaves show signs of maturing. At this time it will be found that new buds are well formed. The plants are then lifted, planted out in Lily-pans and kept perfectly dry and warm during the summer. Care must be taken in the fall to keep them cool, to prevent their starting prematurely. Under such treatment fair success is had here. All the species are quaint and odd in form and coloring. For instance, *I. Suwarowi* has standards lined with blue and edged with golden-brown; the styles are also brown, the crest a bright blue and the falls also lined with blue and with a dark blue signal. *I. Korolkowi* concolor is of a pure heliotrope hue. *I. lupina* has a curious combination of yellowish green with black dots and linings. *I. nigricans*, a new species, is somewhat in the way of *I. lupina* in coloring, varying in hue and in forms of petals. Professor Forster and others have hybridized many of these Irises and the hybrids are as quaint as the parents. One of these, *I. parkor* (*paradoxa* × *Korolkowi*), blooms very freely here and has richly colored dark purple flowers, the hairy signals being a rich plum-purple color.

Elizabeth, N. J.

J. N. Gerard.

#### Flower Notes.

**F**LOWERING plants of *Primula Japonica* in crimson and white have been the prettiest things for table decoration we have had this spring. They were raised from seed last spring and grown in six-inch pots. When autumn came they ripened crowns and were kept with a limited supply of water in a cool pit until spring, where they have been brought into bloom without heat. In sheltered spots these Primroses are hardy. The broad handsome foliage resembles that of the common Primrose and has a distinctly rosette-like arrangement. The flowers are borne in successive whorls on lofty scapes, sometimes over two feet in height. It is a giant among Primroses.

Compared with this, *Primula cortusoides* is a gem. Its small, rounded, slightly hairy, sinuate leaves hug the ground, and from this mat of leaves arise slender scapes of lo<sup>u</sup> bellate rose-colored flowers. There are several named varieties, but so far the type has proved the hardiest. It has rhizomatous roots, which creep over or very near the surface, and on this account the plants need slight protection in winter. A few forced plants of the double white English Primrose bloomed nicely in the cool greenhouse during the late winter months. They make two or three new crowns during the winter. After the blooming season we divide them to single crowns and plant them out in a shady corner. Care should be taken that the long fleshy roots go as deeply into the soil as their length allows, or they will suffer during dry weather.

The double *Lychnis Flos-cuculi*, Ragged Robin, has proved a most useful winter bloomer. The attractive, semidouble pink flowers are borne abundantly all winter; in fact, it is scarcely ever out of bloom. It is quite hardy with us, and increases freely, as any bit of stem will root. In this way it would be possible to get up a large stock of it in a short time.

The rock garden and its surroundings in the grounds belonging to Professor Sargent, of Brookline, Massachusetts, are very attractive just now. The adjacent shrubbery, wooded and grassy slopes are covered with an undergrowth of *Narcissus Poeticus*, Squills and wild Tulips. Large numbers of bulbs have been used in an effective, yet most natural way. On the rock garden conspicuous are large patches of *Daphne Cneorum*, which, owing to the mildness of the past winter, is looking fine everywhere. *Orobis vernus*, the spring Vetch, with rosy Pea-like flowers, changing to purple, is evidently well suited as to location. We have found it hard to establish, though succeeding well enough with other species. The white and blue Grape Hyacinths are remarkably neat. *Trollius Europæus*, with large incurved Buttercup-like flowers, is interesting at all times. It has a long season of bloom, ripens seed freely, which germinates slowly. Seed sown last spring did not come up until this, while the bulk of a lot sown last autumn is up at the same time, but not all, and probably if we hold over the seed-box until next spring there will be another installment to come up. It is the same with many species of *Clematis*, *Hellebores* and other members of the *Ranunculus* family to which the *Trollius* belongs. *Fritillaria gracilis* resembles our common *F. meleagris*, odd, if not beautiful. *Stellaria Holostea* is pretty when in bloom, large sheets of white star-shaped flowers, a rapid grower and a good carpet plant for shady places. If obtrusive it can easily be disposed of, and so does not become a nuisance in the way *Anemone Pennsylvanica* does. The double Vernal Anemone remains in bloom when the single form is long past. *Ajuga reptans*, with spikes of blue, is not as showy as its deeper-tinted relative from the Alps of Europe, *A. alpina*, but is a better carpet plant, and capital for covering bare spots in shady places near water. *Alyssum saxatile* in the sun are sheets of yellow. *Iberis sempervirens* is a mass of white cruciform flowers. Vernal Snowflakes remind one of the cottage gardens of England. *Primula cortusoides* is even better this year than last, is well established and blooming profusely. Its rose-colored flowers are as nearly perfect in tint as one could imagine.

Wellesley, Mass.

T. D. Hatfield.

#### Notes from the Rock Garden.

**N**O part of the garden is so interesting at this season as the rock garden. Last winter was favorable for hardy plants, and with abundant rains recently and warm weather now no nook or crevice is without blossoms to delight the lover of early-flowering hardy herbaceous or alpine plants. Perhaps none of these plants has greater interest than *Dryas octopetala*, especially to me, for during the past six or seven years I have several times raised plants from seed, but have never been able to have them live long enough to come into flower. At last, however, I have been successful, and now there is a beautiful patch of this lovely, modest plant well covered with flowers. The plants were raised from seed some two years ago and were grown in pots until the beginning of last September. They were then transferred to the rock garden where they grew during autumn. They came through the winter in perfect condition. They are in a slightly elevated position in rather deep light soil, where I expect they will grow and spread rapidly. The name was taken from the wood nymphs to whom the Oak was sacred and applied to the plant because the young leaves of *D. octopetala*, on which the genus was founded by Linnæus, resemble small Oak leaves. The plant is low, shrubby and evergreen, with simple, obovate or subcordate, crenately serrated leaves, white and downy beneath. The

flowers are white, slightly more than an inch in diameter and with many yellow stamens in the centre. In fact, the flowers resemble the small, white, single, upright roses. They are produced singly on upright peduncles four or five inches long. It is a native of the cold regions of the northern hemisphere.

Another interesting plant from eastern Russia, which has taken good hold among the stones and rocks, is *Dracocephalum nutans*. This makes a good rock plant. It self-sows its seeds in the crevices, where they grow up and blossom in the spring. It is six or eight inches high when in flower. The whorls of blue labiate flowers are disposed in long nodding racemes, and the stems are clothed with petiolate, ovate, crenated leaves.

Skirting the edges of some large stones, where the soil is cool and moist, *Lathyrus palustris* is growing well and blossoming freely. In such a position this is a pleasing plant. It is about one foot in height, and the peduncles have four or five variegated blue and purple flowers. *Globularia trichosantha* is a mass of blue flowers. It is a choice rock-garden plant and flourishes in an open position in deep light soil. It is exceptionally hardy and withstands the most severe winters. It is six or eight inches high. The light blue flower-heads are pleasing and distinct and are produced plentifully for a long time. *Globularia vulgaris* is also in blossom; the two species are similar, but *G. vulgaris* does not grow as tall as *G. trichosantha*.

The pale blue flowers of *Phlox stellaria*, which are a different color from all the flowers about them, make this plant very desirable. For masses of yellow there are no better plants in blossom now than *Alyssum saxatile* and *A. geminense*, *Erysimum pulchellum*, *Viola lutea grandiflora* and *Papaver nudicaule*. For the best effect these plants must be grown in large masses where they can be seen from a distance. The best white-flowered plants now in blossom in masses are different species of hardy Candytuft, *Iberis*; a half a dozen species of Rock-cress, *Arabis*, and the *Drabas*, *D. alpina*, *D. frigida*, *D. Altaica* and *D. Johannis*.

*Phlox reptans* mantles the soil among the rocks with its creeping stems and soft green leaves, and now it has thrown up numerous flower-stems six or eight inches high, terminated with deep rose-colored flowers. *P. procumbens* is more dwarf, with flowers of the same color. Both of these showy *Phloxes* are indispensable in the rock garden. *Veronica gentionoides* is the earliest *Speedwell* to bloom. A desirable form here is showing larger flowers and longer flower stems than the type; the flower-stems are about a foot in length, and the light lavender flowers are in long loose racemes. The dwarf, trailing *V. pectinata* has pretty small downy leaves and numerous small blue flowers. It is suitable for dry elevated situations.

*Vinca herbacea* is useful and less common than the well-known *Periwinkle*. Its clinging stems among the rocks and the blue flowers nestling among the leaves are pleasing. It grows best in an open position and in slightly moist soil. The lower edges of the rock garden, where the soil is deep and cool, make a good home for large plants of *Dicentra spectabilis*, the most graceful plant now in bloom.

*Scilla Hispanica* is worthy of wider acquaintance. The bulbs are cheap and easily obtained in autumn, and if planted then they are sure to bloom the following spring. The blue flowers are in loose racemes eight or nine inches in length. There is a handsome white-flowered variety also in bloom now. This *Scilla* grows well in almost any soil and should be planted in a mass. In the shade of some trees a bed of *Primula auricula* has been flourishing for the last half-dozen years. These plants are quite hardy, and the beautiful flowers may be counted upon each year regularly. Large masses of *Lily-of-the-valley* fill the air with fragrance as their flowers are beginning to open. This is an excellent plant for shady places under trees, and otherwise unsightly spots may be made green and beautiful with it. The lovely *Aubrietias* are still blossoming. *Orobis vernus* has yet some flowers left, and *Omphalodes verna* is still in good condition. *Anemone sylvestris* is a handsome plant about one foot in height and has large white flowers. It is easily accommodated and grows freely in the rock garden in almost any position.

Harvard Botanic Garden, Cambridge, Mass.

Robert Cameron.

### Summer Pruning the Raspberry.

REGARDING the pruning or pinching back of Raspberry canes in summer, as referred to by Professor Goff in your issue of May 5th, I may say that some experiments which I have carried on for three years corroborate the views set forth by Professor Goff, namely, that summer pruning is, at least in this climate, an injurious practice. The experiments were

begun in 1894. The results, as affecting yield, are shown by the following figures, which represent the number of boxes of berries gathered from each row. The length of the pruned and unpruned rows was the same, of course.

VARIETIES.	YIELD, PRUNED.		YIELD, UNPRUNED.	
	1895.	1896.	1895.	1896.
Heebner .....	90	10	96	19
Springfield .....	32	11	49	17
Royal Church .....	31	3	37	6
Carman .....	25	23	41	39
Thompson's Early Prolific .....	36	21	68	46
Herstine .....	32	11	49	21
Parnell .....	32	11	37	12
Golden Queen .....	40	6	59	17
Brandywine .....	43	..	64	..
Niagara .....	22	12	46	19
Marlboro .....	23	3	27	14
Hansell .....	31	10	47	18
Clark .....	20	8	37	10
Cuthbert .....	35	15	70	11
Turner .....	21	11	50	9
Caroline .....	47	16	64	32

The canes were pinched twice during the summer; the first time at eighteen inches, the second when the laterals had grown fifteen to eighteen inches in length. In this experiment the number of suckers did not appear to be greater in the pruned row than in the unpruned. I am of the opinion that in all sections where winter protection is necessary, Raspberries should be thinned rather than pinched.

Experimental Farm, Ottawa, Canada.

John Craig.

## Correspondence.

### Lilac on Privet Stock.

To the Editor of GARDEN AND FOREST:

Sir,—The past winter has proved the unsuitability of the Privet as a stock for Lilacs, when planted in severe climates. During December and the greater part of January of last winter the ground in this section was unprotected by its usual blanket of snow. The temperature ranged low, fluctuating between twenty degrees of frost and twenty-five degrees below zero, which latter point it touched on two or three occasions. On examining the collection of Lilacs in the arboretum and on the grounds this spring it was found that a large number of those on Privet stock were completely root-killed. The injury to the stock was severest at the collar, where the bark in most cases could be easily rubbed off with the fingers. The union between stock and scions was clearly defined by the limits of the injury upward. The injury downward extended almost to the tips of the roots in some cases, and in others to the depth of a foot only below the surface of the ground.

Lilacs should be propagated by layers; by root or top cuttings when intended for planting where severe cold may find the ground unprotected. It is possible that heavy mulching in the autumn might have saved some of the plants referred to above, but this work is laborious and not always satisfactory in its results.

Ottawa, Canada.

John Craig.

### The Massing of Wild Flowers.

To the Editor of GARDEN AND FOREST:

Sir,—Superintendents of parks and owners of extensive private grounds have much influence in moulding public taste in horticultural matters. Learned works on floriculture or landscape-gardening are read by the few, but the gardener's work is an illustration that he who runs may read. Naturally enough, therefore, his mistakes are copied and his successes patterned after on every hand. It is a gratification to the true lover of our American flora to note that those in charge of extensive grounds are of late years adding more and more of our best native shrubs, climbers and herbs to their planting lists. These plantings, however, rarely show the breadth and plenitude of nature at her best. They show a narrowness of scope, a paucity of effect, as if the authors feared to follow nature in her lavish displays.

It is true that around our villages and through the long-settled portions of our country the flora is scattered thinly, with rarely any breadth or mass of any one species. The fact is, that something like extermination has been going on for many years. But away from the homes of man and the haunts of cattle the

scene is changed. Looking over the unbroken, unbrowsed prairies in June and July we see acres upon acres of bloom. Here one can find a hundred solid acres of Phlox, white, mauve, pink, carmine, crimson and red, and all this dashed with the brilliant red of ten thousand flowers of *Lilium Philadelphicum*. A tiny rivulet, rippling past banks fringed as far as the eye can reach with the mingled scarlet and indigo hues of our two brightest *Lobelias*; a sweep of lowland one solid sheet of azure-blue *Houstonias*, and a wooded hillside thickly dotted with thousands upon thousands of the golden bells of *Erythronium Americanum*; these are other examples of nature's floral wealth that might be multiplied indefinitely, and why could they not be imitated in our large parks, or on a smaller scale in our less spacious ones?

One tires of the artificiality of carpet-beds and formal parterres, and it is doubtful if these things ever gave a tired city toiler a longing for the country. But a bit of nature that tells of the wildwood and the river path is a standing invitation to turn from noisy streets to the country's peace and quietude. If the masses in our crowded cities cannot go to nature for enjoyment, why not bring real nature to them—and nature in one of her most inspiring moods?

Pineville, Mo.

Lora S. La Mance.

### Protecting Roses in Winter.

To the Editor of GARDEN AND FOREST:

Sir,—In Wisconsin we must protect in winter, climbers, such as the *Prairie Queen* and all hybrid *Perpetual Roses*, or they die. In the rural districts this is made difficult by the field mice, which work into the litter, where bush or vine is laid down, or up into the windings of those left erect, and gnaw off the stems to make room for their nests. Many lay their choice *Roses* on the ground and cover with inverted sods and then with litter. This plan succeeds, but is a great task, and uncovering must be done early, or the plant is smothered. The risk of a late frost must be taken.

At my summer place in Lake Mills I have for four years tried the experiment of a rough board housing or "lean-to," otherwise tight, but wide open on the north side. A few dead leaves are scattered around the roots, but nothing more. Covers are kept on until after May 15th. The shoots start late, and are somewhat pale, of course, but never have suffered from the uncovering, and I have never lost wood or failed of a luxuriant bloom.

This plan beats the mice, retards spring starting, and does away with the hurry to uncover. Perhaps the idea is new. At any rate, it is not borrowed and is novel in that neighborhood.

Chicago, Ill.

David E. Bradley.

### Sprouting Pines.

To the Editor of GARDEN AND FOREST:

Sir,—To the interesting notes on sprouting Pines, given in No. 482 of GARDEN AND FOREST by Mr. Pinchot, I can add the following:

(1) The sprouting of *Pinus echinata*, which Mr. Pinchot supposes to have observed for the first time, is, as I have often had occasion to see, a common occurrence over its entire field of distribution. Dr. Mohr, in his monograph on the Timber Pines of the Southern States, on page 98 (Bulletin No. 13 of Division of Forestry), writes as follows about this capacity of the Long-leaf Pine:

"During this season (the second year) adventitious buds appear at the collar of the stem, which bring forth vigorous sprouts, particularly if the stem has sustained the slightest injury. They are apt to form strong branches before the tree has reached its fourth or fifth year. Such branches, which are produced profusely from the stumps of larger trees, scarcely survive another season."

(2) To the Pines which produce persistent sprouts one of the southern species is to be added. Mr. Roth, of the Division of Forestry, now traveling in the south, sends us a specimen of the root of a *Pinus serotina* sapling with the signs of at least two crops of sprouts and a number of living sprouts, the largest of which is at least four or five years old, with a length of nearly four feet and twenty millimeters diameter at the root-collar. Mr. Roth states that hundreds of cases of such sprouting can be observed on an acre, some of those seen being ten years and more old. Logs as well as scrubby trees, much like those of *Pinus rigida*, are clothed along the stem with short sprouts.

This Pine, by the way, known to the loggers as "Marsh Pine," forms a considerable proportion of the lumber cut along the seacoast of North Carolina, where, with *Pinus palustris*, it

covers extensive flats, or, with *P. Tæda*, goes into the marshes, often replacing *P. Tæda* and becoming the only occupant.

It develops nearly as well as the latter, averaging about one foot in height per year, and in six years making a diameter of thirty inches, with forty feet of log-length. It bleeds freely, and is bled for turpentine, as it seems all the southern Pines now are, with the exception of *Pinus glabra*.

While this capacity for sprouting is interesting physiologically, it can hardly be of economic value, except where, as in the Jersey plains, to keep a vegetable cover in spite of the recurring fires, may be of future benefit.

Washington, D. C.

B. E. Fernow.

### Recent Publications.

*Die Nadelhölzer des Cilicischen Taurus.* By Walter Siehe. *Gartenflora*, March and April, 1897.

In these short papers an interesting and vivid account is given of the coniferous trees indigenous to the long mountain range on the south coast of Asia Minor. The northern slopes of the mountains have been entirely laid waste by the wanton destruction of the forests for the use of silver smelters, and the trees referred to occur on the southern slopes, and in many cases have been preserved owing to the inaccessibility of the regions where they are at home. The Turk is not the best forester in the world, and of forest management there is none at all. A piaster (five cents) will purchase a tree, and any wandering shepherd is liable, for an evening's entertainment, to set fire to a Cedar of Lebanon, which, if properly hewn and transported a three days' journey to the coast, would realize a small fortune.

Among the trees noted, the Lebanon Pine, *Pinus Brutia*, Ten., is the most widespread of the Cilician conifers, and forms vast forests at an altitude of from 400 to 1,500 meters. It is a magnificent tree, much resembling *P. Strobus*, L., in its habit. The forests are very dense, and many of the trees reach a height of thirty meters, of which twenty meters show an absolutely erect, branchless trunk. Higher in the range, from 1,500 meters up to the Cedar zone, the Black Pine, *P. Laricio*, Poir., var., is encountered in quantities; a fine tree, with smaller cones than those of the type. *Abies Cilicica*, Ant. & Ky., is abundant, and more famed for its stately beauty than for the usefulness of its wood. In the forest near Namrun it attains a height of more than thirty-five meters, with a diameter of three-fourths of a meter, and preserves its branches down to the ground. In some parts of the range it forms dense forests, to the exclusion of other species, and thrives up to an altitude of 2,000 meters. The highest forest region is the most interesting in the mountain chain, for there, in company of *Pinus Laricio* and *Abies Cilicica*, is found that most magnificent of all trees, the Cedar of Lebanon, *Cedrus Libani*. On the mountains from which it takes its name it is all but extinct; in the Taurus, however, it thrives in great luxuriance, and has been preserved owing to the remote and almost inaccessible crags where it thrives. It is rather widespread, and extends from the Lycian Mountains to the Euphrates, rarely descending below the 1,200 meter level. It grows in open forests, each tree standing alone in stately grandeur, the straight, slender trunks not rarely one meter in diameter and forty meters in height. The cedar-wood is very valuable and twice as costly as that of the Pines. It is yellowish, very close and deliciously fragrant. Its durability was appreciated even when the Temple was built at Jerusalem, and to-day, cut into the panels whereon "icons" are painted, it is in great demand in the Greek Church. *Taxus baccata*, L., is occasionally encountered, usually only solitary and scattered specimens, some of which attain the considerable diameter of half a meter. Curiously enough, the principal factor in their preservation has been the fear of a certain legendary and revengeful nymph, and it would be very difficult to give their age. The Oriental Cypress, *Cupressus sempervirens*, L., is rare in the range, and it is noted that the pyramidal form of the tree, so frequent in eastern cemeteries and elsewhere in ornamental planting, was only seen a few times in the wild state.

## Notes.

The general catalogue of the Southern California Acclimatizing Association has once more come to this office from Santa Barbara. The list of plants is very interesting and valuable for planters in the southern states, and the hints for cultivation make the little pamphlet what it claims to be, a guide for gardening in the south.

*Nymphæa alba* and *N. Laydekeri* were in flower in this vicinity last week. These will be closely followed by *N. carnea*, *N. chromatella* and others which are now showing buds. The continued low temperature of the season has checked the tropical Lilies, though, perhaps, few have yet been planted out by prudent growers. With the exception of the Cape Pond-weed, *Aponogeton*, there do not seem to be any exotic aquatic plants which rival in earliness of flower our native Marsh Marigolds and Arums.

The last issue of the New York *Fruit Trade Journal* gives an account of a newly planted Grape-fruit grove in Florida, said to be the largest in the world. The soil is virgin hummock land which, within a year, was cleared of massive Oak and graceful Palmetto trees and comprises above two hundred acres. The tract extends half a mile along the Manatee River and is more than that distance in depth. The land was thoroughly prepared by experienced cultivators of Grape-fruit, and 20,000 budded trees of the best varieties have been planted.

California papers say that nearly two thousand acres of Canaigre will be in cultivation on the big plantations of the Anglo-American Canaigre Company, near Rialto, in San Bernardino County. This is a native plant of the Dock family, whose roots are rich in tannin, and it is expected that 8,000 acres will be planted at the beginning of the next year. The plant is indigenous to many parts of the state, and wild roots are gathered, planted in rows and cultivated like Sweet Potatoes. It is said that tanning with Canaigre can be done much more rapidly than with other material and requires only days where weeks and months are needed with barks.

The first consignment of winter apples from Australia reached San Francisco last week, and in this fruit Mr. Alexander Caw, the State Quarantine officer, discovered the small white larva of an unknown moth. This grub was tunneling in various irregular directions through the apples close to the skin, and the evidence of its industry was manifested on the outside by an irregular discoloration. Every apple was consigned to the steamer's fire-box, for, undoubtedly, if this Australian apple-miner had been landed it would have become a dangerous enemy to the fruit industry of the Pacific Coast, which has so far escaped from the ravages of the codling moth. This is not the first time that this vigilant quarantine officer has saved the fruit orchards and Orange groves of the west coast from devastation by a new pest.

*Fothergilla Gardeni*, a shrub of the Witch Hazel family, and the only species of the genus, which was in flower here a fortnight ago, is rarely seen in cultivation either in America or Europe, although it was introduced into English gardens from our southern Alleghanies 130 years ago. For some reason, perhaps because it is not easy to cultivate, it is not as abundant in England now as it once was, although it is very beautiful when in flower, and has an excellent habit, with abundant deep-colored foliage. It is a compact shrub when well grown, five feet high, with numerous stout stems, and in early spring, just before the leaves appear, it is covered with almost globular clusters of long white stamens, the only showy parts of the flower, which make it a conspicuous object. Although it is not found naturally north of North Carolina, it seems to be perfectly hardy in New England, and it flowers profusely in the Arnold Arboretum, although it does not ripen seed. It was figured in this journal, vol. viii., page 445.

The first car-load of California cherries arrived in this city May 19th, when the best grades of favorite varieties brought from \$4.30 to \$6.25 a box, wholesale, the highest prices ever paid here at auction for this fruit. Early Purple Guigne, considered the earliest good cherry, was the first arrival this year; it is of medium size, sweet and juicy. The dark varieties thus far have been of better quality than those of lighter color. Among the dark sorts seen here now are Early Black Guigne, known also as Baumann's May; Black Tartarian, the best of all the black cherries, and of the largest size when fully mature; Knight's Early Black, Guigne Marbrée, the old and well-known May Duke, of rich subacid flavor, and California

Advance, a seedling of Early Purple Guigne. Rockport Bigarreau, Belle d'Orleans and Governor Wood are among the light-colored cherries now in season. Thirty cents a pound is the average price of this fruit in the retail stores, but much of it doubtless remains unsold at this high rate, especially as only a small portion is fully grown and ripe. The first Florida peaches arrived on the 19th instant. The variety known as Honey Sweet has been most abundant, with a few crates of Bidwell. New-crop pineapples are also coming from Florida. Strawberries, from North and South Carolina, and from Maryland and Delaware, are in our markets, together with the first pickings from New Jersey.

Professor Card, of the Nebraska Experiment Station, has been making a study of wind-breaks and publishes a bulletin which embodies the experience of a large number of farmers and fruit growers, both in the east and in the west. A very considerable majority of the writers from all sections of the country believe in the value of wind-breaks, but widely different reasons for this faith are given. The western growers consider the protection against the hot winds of summer as the highest use of wind-breaks, while in the east the protection against windfalls is considered the most important by fruit growers. In the west, too, the saving by the prevention of windfalls is recognized, but of still greater importance is the protection against evaporation of moisture from the soil by winds, which is mentioned in letters from all sections. The western growers protect their land chiefly on the south and west, while the eastern growers need protection on the north and west. The observations at the station bear out in a striking way the opinion expressed by many growers that wind-breaks are of great value in reducing evaporation from the soil. The water contained in samples of soil showed a decreasing amount of moisture for a considerable distance under the lee of the breaks, and evaporation as measured directly by the evaporimeter accorded perfectly with the results obtained from the soil samples; and finally the measurement of certain plants themselves corroborated both the other tests and demonstrated fully the practical importance of this protection in preserving the moisture in the soil.

The Castor-oil plant has been cultivated since the earliest historic time, and specimens of it supposed to be over four thousand years old have been found in Egyptian tombs. It is perennial in India, its native country, but as it has spread into less congenial climates it has lost that habit, like the Cotton-plant, and is known to us as an annual. It is commonly supposed that the plant will grow wherever Indian Corn will thrive, and this is true where it is meant to be used as an ornament, but a recent circular published by the United States Department of Agriculture points out that it can only be grown effectively in commercial quantities in warm climates, since its only value is the oil content of the seed, and the general truth which is applicable to nearly all oil-bearing plants holds in regard to this one, namely, the warmer the climate the larger the per cent. of oil. Some varieties of the Castor Bean will mature seed in the northern half of the Indian Corn belt of the United States, but the plant cannot be cultivated there so as to yield paying quantities of oil. It needs a deep, fertile, loamy, friable and well-drained soil, and then where the climate is sufficiently warm it will yield from twenty to twenty-five bushels of beans to the acre, containing from fifty to sixty per cent. of oil. The seeds, after being soaked for twelve hours in tepid water, should be set five or six feet apart each way, two in a hill, and when three or four inches high the weaker plant should be removed. The weeds should be destroyed and the ground kept loose by surface stirring. The seed-spikes should be collected as soon as the pods turn brown and before the seeds drop out of the pods in handling, and placed in the sun until the seeds are partly free from the pods. Frequent gatherings are necessary, so that only such spikes are removed as are in proper condition. The seeds are first cleaned; then, after being gently warmed, are placed under a screw-press, which liberates a whitish liquid. This is mixed with water and boiled for some time, and the impurities are skimmed off as they rise. Clear oil is at length left on the top of the water, the mucilage and starch being dissolved and the albumen coagulated by heat forming a whitish layer between the oil and the water. The oil is further clarified by boiling, which drives off the acrid volatile matter. The Italians have a special method of preparing the oil which rids it of its nauseous flavor, and in this country medicinal oil is manufactured by cold expression from the crushed beans. The oil is largely used in soap manufacture and for machinery. It is the thickest and heaviest of the oils.

## Common Plants.

EVERY nurseryman's catalogue gives an important place to its list of rare plants, and, of course, the prices of trees and shrubs and herbs which are scarce are higher than those which afford an ample stock to draw upon. This is simply in obedience to the law of supply and demand, which in a general way regulates the prices of every commodity which man desires for use or ornament. In the eye of some persons, however, rare plants are invested with a value which does not belong to them intrinsically. One who has acquired the habit or passion for collecting, places the highest value on objects which are unique. A first edition or the only known copy of a book which in itself is nearly worthless may be a prize for which a book collector will give a small fortune; and in the same way an Orchid which is the only individual of its species known will command a price quite out of proportion to any charm it may have of form or color or fragrance. The case of one who is studying a given genus of plants is somewhat similar. He may want an Iris, for example, to complete his series, and to him the missing plant has an importance that would not belong to it under any other conditions.

All this is readily comprehensible, but there are other people who have a feeling somehow that rarity is in itself an element of beauty in a plant; at all events, if they would not state this broadly, they firmly believe in its converse, namely, that a plant which is common is not desirable. It is this idea which lies at the root of the distinction between "common trees" and "ornamental trees" which we so often hear. This notion was once so prevalent that it was a difficult thing a few years ago to find common American forest trees and shrubs for sale in American nurseries. When Central Park was planted it was easy enough to buy European Birches, Norway Maples and Horsechestnuts, but few nurseries had our own Canoe Birch or Pin Oak or Pepperidge. English Hawthorns could be had by the hundred, but many of our native Thorns were not propagated at all. Spiræas and Kerrias and Honeysuckles from abroad could be had by the thousand, but our native Honeysuckles and many of the best of the Viburnums and other American shrubs were not classed as ornamental plants

at all. Conditions have changed since then somewhat, and the herbaceous plants and shrubs and trees which grow in our own forests and along our waysides have been more freely admitted into the aristocratic society of their foreign relatives, and the fact that a plant is common is not always a reproach to it.

Different plants have different values to planters according to the use that is made of them. Landscape-gardening wherever it is practiced over areas of considerable extent deals properly with scenery; that is, with the permanent features of the land—its roll of surface, its sky-line and distance. The greatest artist in landscape is one who with these fundamental elements and the common trees and shrubs and grass makes a picture which is a unit, and every portion of which helps consistently to give expression to a central idea. This differs entirely from what is called decorative gardening, which is concerned more especially with the detailed ornamentation of more limited spaces. For decorative purposes plants and flowers may be grouped into arrangements which kindle admiration on account of their symmetry of form and richness of color. This is the presentation of beauty for its own sake. It appeals to the æsthetic sense alone and not to the imagination, and through it to our higher nature as a landscape picture does. It is not necessary that a decorative group should be in any sense natural, and plants with foliage of strong color or those that can be trained into peculiar shapes or which have an unusual habit are often the most valuable in such places. They are useful just as stones of different form and color are useful in a mosaic. In decorative gardening a plant of Golden Elder or of *Prunus pissardi* may have the highest value, while the same plants in a natural landscape would be worse than useless, and, indeed, might ruin a quiet picture by their obtrusiveness.

There is another kind of gardening, however, which has been called specimen gardening, and which has many attractions to genuine lovers of plants. To such persons a garden exists for its plants rather than the plants for the garden. It is not a landscape picture that is desired, nor yet geometrical designs of pleasing form and color. It is individual plants that are cherished irrespective of their arrangement, and they may be selected for their rarity or their oddity, or for any other quality that appeals to the fancy of the planter. This makes a pleasant diversion, but it is by no means the highest form of gardening. A wise observer once said that it marked a distinct decline in garden art when a gentleman led you to a point on his estate where he could show you the finest *Cryptomeria* in England, instead of conducting you to the point where you might see the most delightful view.

But we have wandered from our purpose. We set out to make a mild protest against the idea that a plant is not desirable if it is common. A great patron of horticulture once declared that he could get up no enthusiasm for Lilacs because they could be seen at every farm-house door. Now, since there are hundreds of varieties of the common Lilac and many distinct species besides, there is opportunity for gathering a collection of these shrubs, which represent a wide diversity of habit as well as in the form and color of their flowers—many of them rare plants which never graced a farmer's yard. But the common Lilac itself will always be a desirable shrub. It has such intrinsic merit that it cannot be vulgarized by mere abundance. Its habit of growth, the graceful way in which its dense panicles of flowers are carried above the thick leaves, their exquisite color, which has no exact duplicate in the vegetable kingdom; the fragrance, which is their own and unmistakable, will always make this a useful plant. It is hardy, long-lived, and will endure abuse; it is often found by a wayside cabin without a single companion, and yet it is beautiful enough to have been the chief ornament of the home of one of our great poets. It is admired because of its many good qualities, and it will be more and more valued for association by every succeeding generation of plant lovers.

The fact is, that for all practical purposes the cheapest plants are the best. Among the novel introductions every year there are some that will stand the test of time, and as soon as they demonstrate their usefulness they will be common. In order to be widely useful a plant must be easily propagated, it must be hardy and long-lived, and these are qualities that will ultimately make it cheap, just as the Tartarian Honeysuckle is cheap, although one of the most beautiful and indispensable of shrubs. Grass is common, but it is an unfailing refreshment to the eye, and it is so universally appreciated that no one considers Ruskin's glowing description pitched on too high a key. No novice need be deterred from planting trees or shrubs on account of the high price of novelties or rarities. If his purse will allow him to import the most expensive sorts he may find pleasure in gratifying his desires in this direction, but if he buys no others he will discover at last that he has but a sickly lot of incongruities. He will learn that the common plants are the basis of every good collection, and that cheap plants are the most effective in producing pictures which are impressive and permanent.

### The True Purpose of a Large Public Park.\*

THE true purpose of a large public park is to provide for the dwellers in cities convenient opportunity to enjoy beautiful natural scenery and to obtain occasional relief from the nervous strain due to the excessive artificiality of city life.

By large public park is not meant one covering more than a certain number of acres, but one large enough to contain a complete natural landscape, where the boundaries will not be obtrusive; where city conditions will not be unduly apparent; where one may stroll over hill and dale, across meadows and through woods, always amid natural surroundings, for hours, without twice following the same routes; where one may come again and again without becoming familiar with all its interesting localities and natural features; where many thousands of visitors may be enjoying the scenery at the same time without crowding each other; where those who especially seek seclusion may find parts so remote from the boundaries that even if city houses are not completely hidden they become reduced in the distant perspective to inconspicuous proportions as compared with the foliage of trees and other natural objects in the foreground; so remote that the roar of street traffic is less noticeable than the rustle of foliage stirred by the breeze or than the songs of birds and insects.

That the scenery of such a park should be beautiful no one will deny, but that it should be natural needs explanation. There can hardly be such a thing as absolutely natural scenery in a public park near a large city. Fires, pasturing, cultivation, wood-chopping, the destruction or driving away of the wild animals, wild birds and insects, and the introduction of others, have long since ended purely natural conditions about every large city, leaving at best only a general resemblance to natural scenery. Even if a tract of land is still to be found in a comparatively natural condition while in private ownership, it could not remain entirely in that condition after being properly fitted for and used as a public park.

With these limitations in mind, what is meant by the natural scenery of a large public park may be itemized as ordinarily either open meadow, open grassy hillsides or rolling ground, open groves of trees with good turf, dense woods, borders of shrubbery, or low woody or herbaceous undergrowth, water in river, brook, pond or pool, and more rarely cliffs or ledges of rock. These principal features of the scenery again may be divided into their elements of earth or rock surface, water surface and foliage, either ground cover, shrubbery or trees.

In most cases a good deal of grading needs to be done

in places. The original natural surface is wholly or partially destroyed and a new surface is created artificially, but it should be so shaped and finished as to appear natural, or, at least, as closely in harmony with natural surfaces as study and care can make it. Too often, however, through lack of appreciation of the true purpose of a large public park, the grading which must be done, either ignorantly or carelessly, or owing to mistaken ideas as to economy, or owing to personal preference for artificiality, is made as regular and unnatural as possible, so that what might have been done in harmony with the natural scenery antagonizes it and greatly lessens its value for its true purpose. Abundant instances of artificial-looking grading in the wrong place exist in many of our large public parks. The responsibility of park commissioners for this sort of interference with the true purpose of a large public park is generally only in the indirect way of entrusting the work to men not properly trained in park work or by enforcing an unwise economy; for it must be acknowledged that to grade naturally and gracefully usually costs more than to grade formally and stiffly.

The water surfaces of a park need more study and care to make them appear natural in outline and as to their margins than does the general ground surface of the park. Too often park waters are almost as stiff and formal in their outlines and in the shaping of their shores as are the curvilinear distributing reservoirs of waterworks. Here, again, the park commissioners are indirectly responsible for the bad results in consequence of working without the plans and directions of a trained artist or without a foreman trained in producing natural effects in park grading.

The verdure of a large public park is what the eye rests upon almost everywhere, and it is therefore the most important of the natural elements of the scenery. The almost universal ground cover is grass, since no other plant is so well adapted to the purpose of hiding bare earth while enduring, with due care and under sufficient restrictions, the trampling of great numbers of people. But there are places where even grass will not thrive, or where a wilder or more varied effect is desirable. Such cases are very generally ignored in our large public parks owing to a lack of knowledge or of artistic appreciation of the possibilities or requirements of particular cases. If gardeners studied natural scenery more they would almost surely discover many opportunities in parks for the application of what they observed in the country. For instance, a dense natural wood which need not be or cannot be well thinned out sufficiently to permit a good turf to be grown, so that people may properly be allowed to ramble everywhere in it, may often be rendered far more natural and interesting by planting pretty wild flowers in its margins and suitable shrubby undergrowth in its interior. Again, steep, open banks, where it is difficult and expensive, and often unnatural, to maintain turf, can be made far more interesting by the use of low ground-covering plants or shrubbery.

Relief from the nervous strain of an artificial city life is afforded in no way so agreeably and conveniently as by a ramble amid the natural scenery of a large park and by the leisurely contemplation of the landscape. There are many workers in a city who suffer more or less from nervous strain, though often they are not fully aware of it. Where a large public park with ample provisions of natural scenery has been created, it has never failed to be much frequented for this purpose and to afford untold benefit to those who use it. Not only are the quiet and seclusion obtainable in the middle of a large area necessary in affording opportunities for occasional relief from the nervous stress of our artificial city life, but they are necessary to the enjoyment of the landscape of the park. Therefore, not only should conspicuous artificial objects unnecessary for the convenient use of the park be excluded from its natural parts, but noisy and dangerous occupations and amusements should also be kept out of, at least, the middle portions of a large park. In order to have the essential quality of seclusion, a large park should not be attempted on both

\* From a paper read before the recent meeting of the Park and Outdoor Art Association of Louisville, Kentucky, by John C. Olmsted, of Brookline, Massachusetts.

sides of a railroad or important city street if it is possible to avoid it, for even if the landscape could be made to seem continuous across the gap the noise would almost destroy the desired seclusion of a considerable part of it. An extent of natural scenery sufficient to afford the sense of quiet and seclusion so beneficial to the city worker can only be secured where the grounds are ample, and therefore this should be the essential characteristic of a large park. It is the one vital reason for the existence of such a park. No number of small parks can possibly answer the same purpose, however useful and even necessary they may be for other reasons.

Even if the true purpose of a large park has been kept in view during the process of selecting the land, determining upon its landscape features, designing its necessary construction and plantations, it is too often lost sight of subsequently, and there is a marked tendency to artificialize the landscape. But whenever it is thought wise for a municipality to provide special attractions, these should be limited in kind and number and be carefully devised. It would not be wise or economical for a city to destroy or injure broad and beautiful park scenery by introducing artificial attractions into it when these could perfectly well be provided in the smaller squares or in special amusement grounds, which could usually be much nearer the centre of population than a large park, and therefore could be used by more people more frequently and more cheaply. It is customary for cities to provide for certain kinds of amusements which are healthful and innocent, and for certain objects that are instructive and entertaining and for some that are artistic and inspiring, and which cannot be or are not usually supplied solely by private effort. Such, for instance, are formal gardens, statuary, conservatories, botanical and zoölogical gardens, concert groves, electric and other fountains, fireworks and the like; also popular athletic grounds, parade grounds, ball grounds for boys, and facilities for boating and bathing. From motives of expediency it is customary to include arrangements for some of these purposes in large public parks, but they should be placed in their borders, and in such a way that they will do the least possible injury to the more secluded parts of the scenery. Great discrimination is necessary in selecting among these objects those which will least interfere with the primary purpose of a large public park. Those forms of amusement or instructive entertainment requiring large buildings or implying much noise, or which draw large and careless crowds that would be liable to injure the grass and shrubbery and trees of the park, should be excluded. It is good policy to secure suitable lands adjoining a large park which can be held in reserve as sites for public museums, grounds for parades, fireworks, public speaking, baseball and (by flooding in winter) for skating and so on. The park in Brooklyn is exceedingly fortunate in having two very commodious public grounds adjoining it. It is greatly to be desired that other cities should do likewise.

If there were a well-established and clearly recognized custom controlling what artificial features might and what should not be introduced into large public parks, such customs would develop into rules of common law. Or if there had been carefully drawn and detailed statutes passed upon the subject, or if there had been a series of decisions of courts as to what buildings and other objects could legally be introduced into public parks, their true purpose would be more clearly understood. It is true, there has been for years a statute in New York state forbidding the erection of buildings above a certain size not strictly for park purposes in any public park, but the principle upon which this law is based is so little understood that a few generous individuals recently had no difficulty in getting a special law passed which enables them, with the consent of the Park Commissioners, to introduce a great museum of history into one of the most beautiful landscapes of one of the most perfect large public parks in the world. The usual arguments in support of this desecra-

tion have been urged, namely, that the building is for a worthy semi-public object; that the collection it is to contain will be interesting and instructive to the public, and that the building itself will be handsome, and consequently that it will be an ornament to the park. If this argument is sound for one such building it is equally sound for others. In that case a large public park is little more than a tract of beautiful vacant building lots which the public is temporarily enjoying as a playground until it shall be gradually required for one public or semi-public building after another. If there is no principle upon which the advocates of the first semi-public building can be refused a site, there is no logical reason for refusing sites to any subsequent projects of a like sort. The bars once let down, there will be a stampede to secure beautiful building sites free of cost for natural history, art, botanical and other museums; for armories, normal colleges, high, grammar and primary schools, and so on almost indefinitely.

#### Proposed Enlargement of the Missouri Botanical Garden.

THE project for enlarging the Missouri Botanic Garden is about to be realized, and Professor Trelease has kindly described the main features of the plans now in the hands of the Messrs. Olmsted. In providing for the future of the garden the Director says the three principal objects to be kept in view are "beauty, instructiveness and adaptability to research." He further says of the grounds and plant-houses, "extensions and changes should be conducted on lines decided upon definitely in advance and be adhered to as closely in detail as the ever-changing conditions may permit, so that each step taken shall be part of a definite, carefully considered general plan, the aim being to develop experimentally along all lines, so that inevitable mistakes can be easily detected and promptly rectified." It will be the aim to make the beauty of the grounds a distinct factor in the collection without sacrificing any of its value as an institution of scientific research.

A tract of between eighty and eighty-five acres of farm land, belonging to the Shaw estate, that adjoins the present grounds on the south-west, will form the addition. After reserving space for the necessary farm-buildings, nurseries and compost grounds, the tract is to be divided into three parts. About one acre will be set apart for developing such transient synopses as are found necessary or desirable. Twenty acres will be used for a synopsis of the North American flora, and sixty acres for a general synopsis of the flora of the world.

On the first division certain small synoptical collections will have place as they are required, no one of them being maintained longer than a few years. These collections may represent medicinal, fibre, forage and other economic plants, or they will illustrate certain botanical works or explain various interrelations between plants and animals, such, for instance, as the pollination of flowers; or they may illustrate the dissemination of seeds or the sleep of plants; or they may show how plants climb, how they catch insects and the like.

The second division lies south of the arboretum. Here it is intended to establish and maintain a synopsis of the flora of the United States, arranged as an attractive piece of landscape-gardening. Every order found in the United States, except parasites, will be represented in this section. It will, of course, be impractical to use all the species, but typical genera of each family can be represented by a few hardy, characteristic species, including the most effective, most interesting and most easily cared for. In this synopsis the so-called natural system of classification, as used in Gray's *Manual*, will be followed in the grouping or sequence of the orders. And the main walk will be the thread connecting the groups, some lying along it, others farther back, but all systematically arranged in relation to it, and easily found when the method is understood.

The third division, comprising the not less than sixty remaining acres of the present pasture, will be devoted to the general synopsis of the flora of the world, where it is intended to show every family that can be cultivated in the open air in this climate, omitting all that are included in the North American synopsis except those that are represented only in the United States. Only a few hardy, decorative and easily cared for species of each family will be used. In this synopsis the classification will be according to what Professor Trelease speaks of as the German system, the nearest approach to which is seen in *Pflanzenfamilien* of Engler and Prantl, and it will be the first planting exposition of a system which brings together not only those plants having evident relationship, but those having a common ancestor.

Under this dual system an object-lesson will be given in two types of classification; the vegetation of the United States will be set forth so that every visitor can become familiar with our native flora with the minimum of exertion and time. Besides this, the pleasing landscape effect produced by the artistic grouping of hardy native species on the twenty acres devoted to native plants will teach a third lesson which ought not to be lost upon the visitors to these popular grounds.

As soon as working plans are adopted the twenty-acre tract will be underdrained and graded, and it is hoped that this part of the work can be completed during the present season, so that the trees and the shrubs can be planted next spring, and the herbaceous material the year following. If the walks are completed the fourth year and the lawns the fifth year, by that time some five thousand species will have been established. Just when work on the ground for the general synopsis of the flora of the world will begin it is impossible to say, but it is intended during the present year to increase the greenhouse space and erect a Palm-tower twenty-eight feet square, in which benches will be abandoned, and everything will be planted out. The management expects to build within ten years a large Palm-house and conservatory, to be placed in the arboretum back of the present parterre, which will be enlarged, and opposite the main entrance to the garden.

Brighton, Ill.

Fanny Copley Seavey.

## Foreign Correspondence.

### London Letter.

**CELMISIA MUNROI.**—This is one of the handsomest of the many species of *Celmisia* which are natives of Australia and New Zealand, where they are known as "Kid-glove" plants on account of the white felt which clothes the leaves of most of them. Beautiful as they are known to be, however, they have hitherto baffled the collectors who have tried to introduce them into European gardens, plants perishing on the voyage and seeds losing their vitality before they arrive here. Only three species have been introduced, namely, *C. Lindsayi*, figured in *The Botanical Magazine*, t. 7134; *C. spectabilis*, *The Botanical Magazine*, t. 6653, and the species under notice. This was introduced by Messrs. J. Veitch & Sons a few years ago, who have or had a large stock of it. A figure of it was published in *The Botanical Magazine* last year, t. 7496. It is now in flower in a cold greenhouse at Kew, the flowers being three inches across, Daisy-like, with white ray-florets and a small yellow disk. The leaves are lanceolate, nine inches long, covered with silky hairs. It is planted in sandy peat and is kept in a sunny position. The leaves are almost as silvery as those of the Cape Silver Tree.

**OLEARIA INSIGNIS.**—The Australian and New Zealand genus *Olearia*, which is a near ally of *Celmisia*, is largely represented in European gardens, some of the species forming large shrubs and proving hardy in the warmer parts of England. The species under notice is, however, too tender for out-of-door cultivation here, but in a cold greenhouse it is happy, growing very slowly, ultimately

forming a dwarf thick-stemmed, branched, low shrub, with oblong leathery leaves six inches long, the under side covered with a thick whitish felt. The flower-heads are produced singly on axillary peduncles six inches long; they are shaped like those of the Cornflower, *Centaurea*, and are two inches across, the ray-florets overlapping, toothed at the apex and white, the disk-florets yellow. It will be seen that this species differs very widely from the rest of the cultivated *Olearias*. It is a native of rocky river-banks in Middle Island, New Zealand, whence it was introduced about ten years ago. There is a good figure of it in *The Garden* for 1888. It is now flowering at Kew.

**DIMORPHOTHECA ECKLONIS.**—I noted this plant last year as a new introduction from south Africa of subshrubby habit, with large Daisy-like flowers colored purple outside and white within. It was grown at Kew as a summer bedding plant, and attained a height of eighteen inches, flowering freely from July onward till the frost came and killed the plants outright. Some plants grown in pots and wintered in a cold house have been a surprising success, the stems being quite woody at the base, the branches leafy and three feet high, and the flowers most abundant all through the spring. The leaves are lanceolate, toothed and about five inches long, and the flowers, which are three inches across, are an elegant white, with a pale blue disk, the reverse of the ray-florets being purple. They close unless exposed to sunlight, as do the *Gazanias*. Messrs. Veitch & Sons are working up a stock of this plant for distribution. It is easily propagated from cuttings. The Kew plants were raised from seeds collected near Port Elizabeth. A figure prepared from one of them has lately appeared in *The Botanical Magazine*.

**CAMPANULA BALCHINIANA.**—This pretty little plant obtained a certificate last year when it was shown by Mr. Balchin, of Hassocks, who stated that it originated from a cross between *Campanula fragilis* (*hirsuta*) and *C. isophylla*. I lately saw the plant in quantity, and after careful comparison I am convinced that it is simply a variegated sport from *C. fragilis*. Whatever its origin, however, it is a beautiful addition to the small trailing *Campanulas* which grow freely either in the sheltered border, on the rockery, in pots or in suspended baskets. Every one knows the value of *C. fragilis* for these purposes, and *C. Balchiniana* is *C. fragilis* in everything except leaf-coloration, and in this it is a charming mixture of creamy-white green and rose-pink, the latter color being most conspicuous on the young leaves. I anticipate for this plant much popularity. It will probably be greatly valued for carpet bedding. Grown in baskets it is a superb plant. The stock has been secured by Messrs. Veitch, who are sending it out as a new plant this year.

**LESCHENAULTIA BILOBA.**—Twenty years ago one might have found half-a-dozen species of *Leschenaultia* among the popular greenhouse plants grown in England; now only one is grown, and that by very few cultivators, most of those who essay its cultivation failing miserably. It may be called a shrubby *Lobelia*, the branches and leaves being soft, otherwise heath-like, and the flowers of a bright sky-blue color. A well-grown specimen is one of the most beautiful of pot-plants. The most successful grower of this species is Mr. Balchin, of Hassocks, near Brighton, in whose nursery I lately saw large batches of it in various sizes. They are grown in the same kind of soil and treated in the same manner as *Erica hyemalis*, with this essential difference: *Leschenaultias* have fleshy roots; they are therefore able to bear drought, and Mr. Balchin says the only secret there is in their management is that they must be kept dry all through the winter. If they flag give them a little water, but do not give them any more until they flag again. In a cool house with an ash bottom they require no water for months.

**BORONIA HETEROPHYLLA.**—There is no more beautiful greenhouse plant than this. Unfortunately, however, it resembles its congeners in being somewhat difficult to grow, although any one who can manage *Epacris* can

Fig. 27.—*Cladothamnus pyrolæfolius*.—See page 216.

1. A flowering branch, natural size. 2. A fruiting branch, natural size. 3. Vertical section of flower, enlarged. 4. A stamen, front and back views, enlarged.

grow this *Boronia*. The best grower of it that I know treats the plants exactly as he treats *Epacris*—that is, in March or April he cuts them in hard, places them in a warm moist house to break, repots them in a mixture of peat and sand when the new growth is half an inch long, and keeps them warm until July, when they are gradually inured to a lower temperature and more air, and are finally placed in a cold house. Grown in this way plants in five-inch pots are perfect little specimens, eighteen inches high, crowded with branches which are bent over with the profusion of bright rose-crimson bell-shaped flowers. In a cool house the plants bloom in April and remain in flower about two months. This species was introduced to Kew about fifteen years ago by Miss North, who found it wild in West Australia and described it as "very beautiful, scent delicious, quite unknown."

*CYPRIPEDIUM SPECTABILE*, var. *ALBUM*, a pure white-flowered variety of the Moccasin Flower, is the most attractive Orchid in flower at Kew. It is not what is generally known as the white variety, which has a tinge of rose in the segments, but is pure snow-white. We grow a large number of plants of this *Cypripedium* in pots in a cold house or frame and they flower in May, when they are worthy of a place among the choicest of cool-house Orchids. Of course, we grow it largely in the open air as well. The best examples of it that I have ever seen were growing in boggy soil on the edge of a pond, the treatment being almost sub-aquatic; they were large, healthy clumps of stems two feet high, each bearing two, a few of them three flowers. We also grow them in pots for the cold house and flower them in May; the Japanese Lady's-slipper, *C. japonicum*, and the large, handsome *C. macranthum* from Siberia, *C. pubescens* and *C. acaule* also flower with us in May when grown in pots.

*CYTISUS KEWENSIS*.—This is a hybrid between *Cytisus albus*, the white Portuguese Laburnum, and *C. Ardoini*, a yellow-flowered prostrate species from the Maritime Alps. It originated in the Kew Arboretum, where there is now a bed of it in flower. It promises to be a useful plant for the rockery and for small gardens, as it is of dwarf, almost prostrate, habit, with small hairy leaves and cream-yellow flowers, resembling those of *C. præcox* both in size and color. It is perfectly hardy. Some plants of it were shown at the last meeting of the Royal Horticultural Society and were much admired. *C. præcox* is magnificent at Kew now, two very large round masses of it in a conspicuous position on a lawn being literally clouds of pale yellow flowers. It will be remembered that this most useful hardy shrub is the result of a cross between *C. albus* and *C. purgans*.

## New or Little-known Plants.

### *Cladothamnus pyrolæfolius*.

*CLADOTHAMNUS* is a genus of woody plants of north-western America of the Heath family. The original species, *Cladothamnus pyrolæfolius*,\* is distinguished by solitary five-petaled flowers terminal on short leafy branches, or rarely axillary, anthers opening laterally for about half their length with narrow, elongated, terminal pores, and five or six-celled globose capsules. It is a glabrous shrub with slender reddish upright stems from four to ten feet tall, clothed with thin obovate lanceolate mucronulate, nearly sessile, pale green leaves from an inch and a half to two inches and a half in length and about half an inch in width, and flowers nearly an inch across when expanded, their light reddish or pink petals, which are rather longer than the acute foliaceous calyxlobes, being exceedingly evanescent.

*Cladothamnus pyrolæfolius* grows along the borders of

the upland meadows of Alaska, where it opens its handsome flowers in succession during several weeks in summer.

Professor Green has recently shown that a second species of *Cladothamnus*, long confounded with the Alaskan plant, which he describes as *Cladothamnus campanulatus*,† inhabits the high mountains of Washington and British Columbia, and differs from the type of the genus in the glandular hairs on the margins of the sepals, in its campanulate corolla with petals joined into a short tube, and in the dehiscence of the anthers, which open only by large terminal pores. The leaves are short-stalked and clothed on the under surface of the veins and on the petals with reddish hairs, and the flowers are solitary, in pairs, or in threes, from lateral buds, and are borne on short hirsute pedicels.

*Cladothamnus* has probably not been successfully introduced into gardens. The Alaskan species might flourish in those of western Europe, although it would probably not thrive in the eastern states. The other, which appears to be a rare plant, might possibly grow in our gardens, where the attempt to cultivate it is certainly worth making. Our figure of *Cladothamnus pyrolæfolius*, on page 215 of this issue, is from a drawing made by Mr. Faxon from a specimen collected by Mr. M. W. Gorman in 1893 on the woody borders of upland meadows near Short Bay, Alaska.

### The Rock Garden in May.

THE rock garden is never more interesting than during the month of May. The Moss Pinks, forms of *Phlox subulata*, are in the height of their beauty; compacta, pink; atropurpurea, purple; Fairy, white, tinted with rose; Model, carmine; The Bride, white; and Sadie, a lovely true blue, a sport from *Phlox subulata nivalis*. The color-contrasts obtained by planting these with Iceland Poppies, bright yellow *Alyssum Gemoneuse*, perennial Candytufts and scattered Columbine is truly charming. *Anchusa Barretieri* is new to us and one of the handsomest Alkanets we have ever grown. It is comparatively dwarf, not more than a foot and a half in height and bushy and free. Like the majority of the Borageworts, to which family the Alkanets belong, the flowers are deep blue. Columbines (*Aquilegia*) in variety are an attractive feature, but of late years the borers have destroyed large numbers of plants, and to keep up a display of the choicer kinds losses must continually be made good from our reserve garden. The chrysantha × cœrulea hybrids are hardy and free, giving all the shades possible between blue and yellow. Whatever may be said against the natural crossing of the different types of these plants, they are at least interesting, and to the uninitiated just as handsome. The distinct but commoner *Aquilegia Canadensis* has been improved by the infusion of alien blood, so that now we have varieties with larger flowers, mostly later blooming, and varied colors. The true *A. Olympica*, blue and white, is one of the handsomest Columbines. *Iris verna*, sweet-scented, lavender-flowered—an American species—is among the prettiest of dwarf Irises. *I. oxysepala* is a hardy Siberian kind with slender tough leaves and lilac-colored flower. *Centaurea montana*, with heads of blue, and silvery foliage, is worthy a place anywhere. *Verbascum phœniceum*, in bloom, is curious, if not beautiful; all its leaves are radical, primrose-like, hugging the ground in a rosette, from the centre of which comes a leafless scape a foot or more in height, with rotate flowers for the most of its length in colors varying from dull purple to white. *Viola cornuta*, in several varieties—Perfection, mauve; Magnifica, purple, and Lutea—is continually in bloom. Neat-habited, healthy plants like these are always pleasing. *Phlox reptans* and *P. amœna* are two rosy-colored varieties, and *P. divaricata* comes in shades between blue and white. Besides the Iceland Poppies, which we have had from the opening of spring and shall have until autumn, there will be a temporary display of the gorgeous oriental kinds in crimson and orange tints, while *Papaver rupifragum* gives orange-red flowers with an indescribable sheen like changeable silk. About the same time the pale yellow Day Lily, *Hemerocallis graminea*, will be in bloom. The yellow Globe Flowers, *Trollius*, are handsome, never untidy, and continue

\* Bongard, *Mém. Phys. Math. et Nat.*, pt. ii.; *Acad. Sci. St. Pétersbourg*, ii., 37, t. i. (*Fl. Alaska*) (1837).—Gray, *Syn. Fl. N. Am.*, ii., pt. i., 44, in part.—M. W. Gorman, *Pittonia*, iii., 75.

† *Tolmiea occidentalis*, Hooker, *Fl. Bor. Am.*, ii., 41 (1834).

† *Cladothamnus campanulatus*, Green, *Erythea*, iii., 65 (1895).

in bloom a long time. The incurved Buttercup-like flowers are useful for cutting and last well. *Anemone umbellata* is new; the color of its flowers is between yellow and green, and though it may not be handsome, its habit is good, and among a number of types there is room for it. Scattered tufts of the Fire Pink, *Silene Virginica*, give touches of scarlet, and the handsome *S. Pennsylvanica* is not to be despised because it is common. The true Pinks, *Dianthus*, are in bud, and in a few days we shall have the Ragged Robin, *Lychnis flosculi*; Bachelor's Button, the double-flowered *L. diurna*, and the German Catchfly, *L. viscaria*, fully out.

Wellesley, Mass.

### A Few Roses.

ONE welcomes the first Roses not alone for their beauty, but also as an indication of genial weather. The early Roses have a perennial charm and a beauty all their own. Though the species have been known a long time, and are not rare, they seem to be cultivated mostly in large plantations, and make their way slowly into small gardens. Owing to the cool weather, *Rosa rugosa* did not precede the other species at as long an interval as usual, and the Burnet Rose, *R. spinosissima*, followed it closely. This charming little Rose is perfectly hardy, with single creamy white flowers. The leaves are small and the thin stems bear enough prickles to merit its specific name as the very spiniest. It makes a neat bush about three feet high, and is always a striking plant in the hardy border. It is to be had readily from seed, in which way it strayed into my garden from Tenby. I have been told by a high authority that *Polyantha* Roses are not of much account, but there is in the border a Remontant form or hybrid of this Rose which could not well be spared. It is very hardy, forms a bush about three feet high, and bears, during the season, frequent crops of small single flowers of a beautiful pink color.

Another hybrid much valued here is the Dawson Rose, which is now coming into flower. If allowed to grow naturally this is a most beautiful plant at flowering time, when its long shoots are covered with small semidouble pink flowers in clusters, the buds opening in succession. A spray six to nine feet long makes a glorious decoration, and the old wood will soon disappear for that service, much to the relief of my helper, who objects seriously to untrammelled growths. But the growth of this Rose is slight in comparison with that of *Rosa multiflora*, which in wild luxuriance covers twenty-five feet or more of fence, and would probably spread over the entire garden if left unchecked. One is sorry to touch knife to a plant which evidently so enjoys life and in a few days will be covered with myriads of fragrant blossoms. A few, at least, of the large number of single Roses should be in every garden.

The general culture of Roses offers some difficulties in this climate, owing to hot summers and to the special fondness of many species of insects for their foliage. It has always seemed to me that if the small grower would exchange most of his Hardy Perpetual Roses (usually bought under the impression that they were perpetual bloomers) for Teas or hybrid Teas he would have more satisfaction and rid his garden of some unsightly objects, for after the Rose season the plants are usually neglected. Tea Roses produce flowers all the season, and, naturally, their wants are more apt to receive attention. Perhaps, on reflection, that hint will not be of much service farther north than this, though among the Teas some will be found much harder than others. La France requires no protection here; neither does Auguste Guinoisseau (the alleged white La France). There are other surviving Tea Roses in the garden, but the most interesting and promising one is the comparatively new Kaiserin Augusta; ten plants which came through last winter untouched are now growing strongly and are full of well-developed buds. This variety produces an abundance of handsome white flowers continuously during the season, and I know of no Rose of its color which is more likely to give complete satisfaction.

Elizabeth, N. J.

J. N. Gerard.

### Crinum amabile and C. Asiaticum.

CRINUM AMABILE has been much admired in the Palm-house here for the past two or three weeks. This is a noble plant, and when well grown its foliage is strikingly handsome, even when it is not in flower, and when its flowers are open their presence is made known to any one who enters the house where the plant is grown by their delightful fragrance, even before they are seen. This is by no means a new plant, since it was introduced to Europe over fourscore years ago from Sumatra. This genus *Crinum* belongs to the *Amaryllis* family, and the part underground, or bulb, is not very

large. It has a neck about a foot in length, however, and is nine or ten inches in circumference. Its thick, dark green leaves measure four feet in length and four inches in breadth, and they taper gradually to a point. They also arch gracefully and add much to the appearance of the plant. The scapes measure about three feet long and are crowned with umbels consisting of about two dozen flowers. The perianth tube is bright red and is four inches long, and the segments are the same length and color and revolute. The flowers in the umbel do not open all at the same time, and therefore the flowering season is in this way very much lengthened.

Another truly noble *Crinum* which ought to be in blossom in another week is *C. Asiaticum*. The bulb of this plant measures about five inches in diameter and has a neck about a foot in length. Its deep green leaves are long and arching. The plant grown here is about four and a half feet in height and nearly the same in breadth; the flowers are white and produced in umbels of about fifteen to twenty flowers.

*Crinums* thrive in a compost of turfy loam, dry cow-manure and a little charcoal. When they are grown in large pots they do not require annual repotting; in fact, our large plants have not been shifted for the past five years. A top-dressing of good rich soil is all that is necessary, and when they are well established liquid-manure is very beneficial. When the plants are growing they need an abundant supply of water. For large greenhouses where there is plenty of room these stately *Crinums* associate well with such plants as Palms, Cycads, Bananas and *Dracænas*.

Harvard Botanic Garden, Cambridge, Mass.

Robert Cameron.

### April Irises.

WITH reference to the article on page 167, allow me to state that my description of the color of the flowers of *Iris Assyriaca* is based on an average. Among a hundred bulbs twenty are pure white, twenty more milk white, and the rest a bluish white. It is earlier than *I. Sindjarensis*, and if kept dry for three months a very free bloomer. I wonder my friend Mr. Gerard does not mention *I. Bosniaca*, which, although of the rhizomatous section, is here in flower from the 15th of April onward; it is rich, free-flowering, of a soft lemon-color, and the flowers are comparatively large, much better than any in the *Pumila* section, and standing slight frosty nights unharmed. To these spring-flowering Irises the central Asiatic species, *I. Korolkowi*, *I. vaga*, *I. stolonifera* and *I. Leichtlinii* form a connection with the later-flowering kinds of the rhizomatous section. The climate of the United States of America seems to coincide perfectly with the wants of these Irises.

Baden-Baden.

Max Leichtlin.

**Propagating Lilacs.**—Referring to the notes on Lilacs and Privet in the last issue of GARDEN AND FOREST, I would say that while it is plain that the Privet cannot be recommended as stock where it is not hardy, there are many reasons to justify its use elsewhere. In the first place, nurserymen use it because there is no other way to get up a stock of the newer kinds as quickly; but this is not the only reason. The Privet dwarfs the Lilacs and causes them to flower in a very short time, and in a profuse way that rarely occurs when on their own roots, and as dwarf shrubs they are available for a great many purposes. Florists use them for forcing, with certainty of their flowering. As they are usually budded close to the ground they can be set below the union and thus form roots from the Lilac scion, as is often done in the case of the dwarf Pear.

### Correspondence.

#### The San José Scale Disease.

To the Editor of GARDEN AND FOREST:

Sir,—On page 200 of the current volume of GARDEN AND FOREST is a note taken from *The Country Gentleman* regarding this interesting topic. I have a bulletin almost completed on this subject, but an unusual demand has been placed on my time this spring, making it difficult to complete the manuscript. It was my intention not to announce this valuable discovery until the bulletin appeared, but a portion of my report to the Florida Horticultural Society was on this subject, and that seems to have thwarted my purposes.

The earliest intimation of this disease was observed in 1895, but the discovery and experiments were not made until 1896. The experiments indicate that this fungus (*Sphærostilbe coccophila*, Tul.) is an effective and practical remedy for this

scale in Florida, but we are by no means assured that it will be of any value in the north, either east or west. Since, however, extensive experiments are already under way in the east and west, we may look for reports from these sections in reasonable time.

The subject is of such importance that to give information and prevent misconceptions I offer the following general remarks:

1. The success attained by using this fungus from cultures makes it a promising remedy against the San José scale.
2. It is "nature's own remedy," and all that we do is to disseminate it properly.
3. It was discovered on a native scale (*Aspidiotus obscurus*, Coms.) at Lake City by Mr. A. L. Quaintance. Later finds indicate that it is quite generally distributed on these scales (*A. obscurus*) at Lake City and at De Funiak.
4. The fact that it is native to this state insures a constant source of supply and obviates the use of cultures that might have become attenuated.
5. Bread culture can be produced in large quantities at a slight expense.
6. The fungus will doubtless prove an excellent remedy in California.
7. As the scales are killed they wash from the tree, leaving the bark clean and free.
8. Most of the applications of this fungus were made by orchardists, proving that it is possible for the fruit grower who may not be a scientist to apply the laboratory-grown material properly.

Copies of our bulletin may be obtained upon application to O. Clute, Director of Experiment Station, Lake City, Florida.

Lake City, Fla.

P. H. Rolfs.

### May Flowers in Southern Michigan.

To the Editor of GARDEN AND FOREST:

Sir,—The cool weather which has prevailed since frost departed has prolonged the time of April flowers here well into May. In a wooded situation, on the 19th, I found masses of *Phlox subulata* spread over the sandy beach of a lake for rods in extent, giving its share of sweetness to the breeze. The beautiful scarlet pendent flowers of the wild Columbine were swinging everywhere among the delicate greens. For grace and delicacy of flower and leaf the early Meadow Rue, *Thalictrum dioicum*, could scarcely be surpassed as it hung fringing the edge of a shelving bank. *Geranium maculatum* scattered brightness here and there, with *Lithospermum hirtum* close at hand. *Smilacina stellata*, which grew in profusion and exhaled a fragrance somewhat like Lily-of-the-valley. An early Vetch, *Vicia Americana*, is a pretty climber well worthy a place in the garden; it is graceful in vases and keeps well; *Lonicera parviflora*, var. *Douglasii*, was the only Honeysuckle noted in bloom at this date. The flowers are dark red, tinged with yellow. *Actea spicata*, var. *rubra*, has a globular cluster of flowers, white in all their parts except the rather prominent scarlet stigma. The conspicuous fruit of both the *Acteas* in this region makes them desirable for the shady border of a garden. Blue Violets made mats among the shrubs, and more rarely the beautiful *Viola pedata* was seen. Climbers of many kinds are plentiful in all wild places hereabout, and it is surprising that farm-houses so generally lack these graceful decorations. They give to a very humble dwelling a cheerful aspect not attainable by other means.

White Pigeon, Mich.

Dorcas E. Collins.

### Forest Preservation.

To the Editor of GARDEN AND FOREST:

Sir,—It is well known that scientific forestry, while promising only a very small profit on forest capital, is calculated at the same time to make that profit continuous. This offers little inducement to individuals, unless they be rich and desire the forest more than the income; but the National Government, being long-lived, can afford to wait. Towns and communities are in a somewhat similar position, and it would seem only natural for them to provide for a continuous revenue by securing suitable forest land in their vicinity. This ought not to be delayed too long, for with the increase in population and the decrease in forests the prices of forest land will be constantly rising; besides, it will require years to put a "natural" forest into a "normal" state (scientifically speaking).

Of course there are other reasons, often much more significant, for forest preservation. It would be unwise, I think, for a town to acquire forest property for revenue when the same

forest might fitly provide for a future rural park or pleasure-ground. My suggestion is made in the hope that some more of our woods may be saved from general destruction.

Muenden, Germany.

G. F. S.

## Current Literature.

### The Cultivation of Plums.

THE literature on the growing of Plums in this country is very scanty for the reason, perhaps, that the cultivation of this fruit has hardly advanced beyond the experimental stage, except in a few places like western New York and on the Pacific coast. Professor Bailey's notes upon Plums, which have just been published as Bulletin 131 of the Cornell Experiment Station, are therefore very timely. The notes begin by grouping the various types, and this arrangement shows at once how complicated the subject is botanically owing to the number of distinct species from which the cultivated varieties have been derived. The following groups are named:

(1) Domestic or European type, *Prunus domestica*. Native to western Asia. Comprises the common or old-time Plums, such as Green Gage, Lombard, Bradshaw, Yellow Egg, Damsons and the like. The leading Plums from Lake Michigan eastward and north of the Ohio and on the Pacific slope.

(2) The Myrobalan or Cherry-plum type, *Prunus cerasifera*. Native to south-eastern Europe or south-western Asia. Much used for stocks upon which to bud Plums, and also the parent of a few named varieties, like Golden Cherry; De Caradeuc and Marianna are either offshoots of it or hybrids between it and one of the native Plums.

(3) Japanese type, *Prunus triflora*. Probably native to China. The type seems to be generally adapted to the United States, and will certainly be of great value to both the south and north.

(4) The Apricot or Simon Plum, *Prunus Simonii*. Native to China. Widely disseminated in this country, but little grown except, perhaps, in parts of California.

(5) The American type, *Prunus Americana*. The common wild Plum of the north, and extending westward to the Rocky Mountains and southward to the Gulf and Texas. Admirably adapted to climates too severe for the Domestic Plums, as the plains and the upper Mississippi Valley.

(6) The Wild Goose or Hortulana type, *Prunus hortulana*. A mongrel type of Plums, comprising such kinds as Wild Goose, Wayland, Moreman, Miner and Golden Beauty. No doubt, hybrids of the last and the next.

(7) The Chickasaw type, *Prunus angustifolia* (or *P. Chicasa*). Native to the southern states, and there cultivated (from southern Delaware southward) in such varieties as Newman, Caddo Chief and Lone Star.

(8) The Sand Plum, *Prunus Watsoni*. Native to Kansas and Nebraska. A bush-like species, little known in cultivation. A hybrid of this and the western Sand Cherry is the Utah Hybrid Cherry.

(9) The Beach Plum, *Prunus maritima*. Native to the coast from New Brunswick to Virginia. In cultivation represented by the unimportant Bassett's American; also as an ornamental plant.

(10) The Pacific coast Plum, *Prunus subcordata*. Native to Oregon and California. Sparingly known in cultivation, chiefly in the form known as the Sisson Plum (var. *Kelloggii*).

With these ten types coming into cultivation in the rapidly enlarging fruit zones of our immense country, who can prophesy what the final outcome as to types and varieties may be?

This bulletin treats chiefly of the common European type, which includes (1) the Damsons, with small firm fruit, of various colors, borne in clusters, and generally having small leaves; (2) the Green Gages, of which the Reine Claude is the commonest representative in New York, but comprising various other plums which are smallish, green or yellowish green, spherical and of high quality; (3) large yellow plums, such as Coe's Golden Drop and Washington; (4) large colored plums, red, blue or purple, like the Blue Prunes, Lombard, Bradshaw and Quackenboss. These will always be the leading types for western New York, although the Japanese varieties will be useful in adding variety to the list because they have many early varieties, and the fruit is so firm that it carries well. Besides this, the trees are vigorous, very productive and less liable to black-knot and shot-hole fungus than are those of the Domestic type. The Americana Plums are more hardy than either, but they are not to be recommended for market cultivation in New York because they are inferior to the others in quality, and their superior hardiness counts for little since the winters are rarely so cold as to injure the Domesticas.

The plum is a fruit which has no regular standing in the market as pears and apples have, and depends more or less for sale upon the general supply of other fruits. This means that since the plum is of secondary importance in the market commercial growers can easily plant too many trees. The Plum thrives on a great variety of soils, but does best on clayey loam, and usually upon land suited to Pears, or the heavier soils upon which Apples will flourish. The greater number of trees grown in New York are grown on Myrobalan stock, a native of south-eastern Europe and south-western Asia. There are some varieties, however, which overgrow the stock so that it is likely to sprout from the ground and cause trouble. Professor Bailey thinks that the *Domestica* Plum itself is the ideal stock, although it is difficult to secure seed, and the stock is variable and rather likely to be injured in the nurseries by leaf fungi. It is for this reason that the Myrobalan has supplanted it. The Peach is largely used as a stock in the southern states and is gaining favor in New York. It is probably better on sandy lands than the Myrobalan, although some varieties, like the Lombard and French Damson, do not unite well with the Peach. Many varieties of Plums are such slow and crooked growers in the nursery that it is advisable to graft them on some strong straight stock, and the Lombard is undoubtedly the best for this purpose. Plum-trees are usually planted when two years old from the bud, although some of the strong-growing kinds may be planted at a year old. They should be set as far apart as Peaches are—that is, from fifteen to eighteen feet apart each way, or they may be planted eighteen or twenty feet apart one way or from ten to twelve feet apart the other, in which case cultivation in one direction is eventually stopped. When planted the trees are pruned in the same way as Apple-trees are, and it is advisable generally to start tops as low as possible and yet allow the working of the curculio catcher below them. After four or five main limbs have been allowed to form the framework of the top, the central stem is often cut out, but it may be allowed to remain. If the trees become too tall and whip-like they may be headed in, but it ought to be remembered that this upward growth commonly ceases and the tree begins to spread when bearing time arrives. If they seem to be making too vigorous growth it is better to withhold fertilizers or cultivation than to stop it by heading them in, since this only makes the growth stronger.

The black-knot is best kept in check by systematically cutting it out wherever seen, and if the trees are thoroughly sprayed every year with Bordeaux mixture for the leaf-blight the black-knot will make comparatively few inroads into the orchard. The blight which causes the leaves to fall in August or September is one of the most serious diseases of the Plum, but it can be kept in check by spraying with Bordeaux mixture two or three times during the summer. The fruit-rot is also the work of a fungus; the dead and dried fruit may often be seen hanging on a tree all winter, and in such cases it is probable that the fruit-spur will be killed. In handling this disease it must be remembered that some varieties are more susceptible than others. The Lombard is one of the worst. Again, if the fruit grows in dense clusters the disease is more apt to be severe, and therefore the thinning of the fruit is an admirable preventive of this as well as an efficient means of increasing the size and quality of the fruit. The specific treatment for the disease is to spray with the Bordeaux mixture.

The Plum scale has created much alarm, and, although formidable, it may be held in check by thorough spraying with strong kerosene emulsion in the winter-time. Curculio is the most widely known enemy of the fruit. The mature beetle lays eggs in the fruits when they are small; these hatch, and the little maggot bores into them. Attacked fruits ordinarily fall, but if they are not stung until they are half-grown they may adhere to the tree, when they will be wormy and gummy at picking time. Taking advantage of the fact that the mature beetles are sluggish in the morning they may be jarred into sheets or canvas hoppers, which can be moved from tree to tree upon a wheelbarrow-like frame. There is a slit in one side of the hopper which allows the tree to stand in the middle of the canvas, and then two or three sharp jars with a padded pole or mallet will bring the insects down, and they roll into a tin receptacle at the apex of the hopper. An active man can attend to three hundred or four hundred full-bearing trees in six hours.

The most popular variety of Plum, and one of the poorest, is the Lombard. Its merits are its great productiveness, vigor and hardiness. The fruit is only fair in quality, and it ripens when the market is full. It is very susceptible to the leaf-blight and fruit-rot, and yet many orchards planted with this variety exclusively have been successful commercially. Perhaps varieties which are specially early or late and those

which have pronounced colors, especially dark red or purple, will prove the best market fruits. Some dark yellow varieties are also salable, but those of an ill-defined reddish color, brown or light yellow are usually not profitable. And yet the *Reine Claude* is a yellowish green plum. It is saved, however, by its established reputation as a culinary variety. So far as known, Plums of the *Domestica* and Japanese type are self-fertile, but it is always the safest course to plant varieties in alternate rows.

These notes of Professor Bailey's are supplemented by a descriptive list of varieties by Mr. S. D. Willard, who is an excellent observer, and who has had such a long experience in plum-growing that he is a recognized authority in the matter. At various times the Cornell station has published bulletins on particular phases of plum-growing, and these are all referred to in their proper place, so that this little treatise will be found very complete and useful.

## Recent Publications.

*The Fertility of the Land.* By Isaac Phillips Roberts, Director of the College of Agriculture and Professor of Agriculture in Cornell University. The MacMillan Company. 1897.

This is the latest publication of the admirable Rural Science Series, which is edited by Professor Bailey, and its purpose is well set forth in the subtitle as a Summary Sketch of the Relationship of Farm Practice to Maintaining and Increasing the Productiveness of the Soil. We do not mean that because the work is specifically devoted to certain phases of farm practice it ignores agricultural science. On the contrary, the treasures of science are continually drawn upon to explain the fundamental reasons for the ordinary operations of the farm. The very first chapter, entitled "An Inventory of Land," ought to prove of fascinating interest to a young farmer who has never made any estimate of the amount of plant food that is found generally in soils, or of what sort of food and how much of it is required by his crops, or how stores of potential fertility in soil and subsoil can be made available, or how one can learn what elements ought to be added to maintain the supply and increase its usefulness. All this is science, but it is applied science, and science so skillfully adapted to everyday use that it becomes the very philosophy of farm practice. The next chapter on the evolution of the plow and its use in tillage shows how the moving of the soil in the right time and in the right way helps his land in a hundred subtle ways of which the thoughtless farmer has never dreamed. In short, the book will be found helpful to the farmer in that it will enable him to go through the routine of his everyday work with intelligence, and therefore with skill and the assurance of wider success. In an editor's preface, Professor Bailey speaks of the book as the ripened judgment of the wisest farmer he has known. We are told that Professor Roberts has been a successful farmer at the same time that he has been a successful teacher of agriculture and a distinguished experimenter. He has also had the advantage of travel, and therefore his opinions on farm methods ought to be of value. He has the philosophic temper, too, which has moved him to inquire into reasons and results. His book, then, is a record of his own experience and the experience of others in maintaining the productivity of the land; and since this is the fundamental problem in practical farming, its discussion throws light on so many details of farm practice that we agree with Professor Bailey when he says that the book comes as near being a treatise on agriculture as any single volume can be.

Occasionally one comes upon a bit of moralizing that seems a little out of place, or a generalization which the data hardly justify, or a crude statement now and then such as one trained in early life to scientific thinking would not make, but, taken as a whole, it is a singularly useful volume which covers a wide range of subjects, all of which are treated succinctly and yet clearly and with a due regard to their relative importance.

## Notes.

The number of visitors to the Zoological Gardens in Regents Park, London, during the year 1896 was 665,000. The Aquarium of this city has been open less than six months and the visitors so far number more than 700,000.

One of the late farmers' bulletins, issued by the United States Department of Agriculture, is entitled "How to Grow Mushrooms," and has been prepared by William Falconer. It is a miniature treatise comprised within twenty pages, but it gives concise directions for every process, from the preparation of the bed to the transportation of the crop to market in an attractive condition.

This has been an unusually favorable spring for flowering shrubs, since there has been no hot period to force them into bloom, and the flowers have had opportunity to develop slowly, attain their best form and remain a long time. The Virginia Fringe-tree, *Chionanthus Virginica*, is particularly beautiful. Its panicles of pure white flowers hang long and full, and in such numbers as to cover the tree completely as with a mist of snow. The Fringe-tree is dilatory about unfolding its leaves, but, apart from this fault, it is one of the very best of our small trees. Its habit is good, its leaves clean and healthy, its individual flowers delicately beautiful and the flower-clusters unexcelled in grace.

In response to invitations issued to various landscape-architects, park commissioners, city engineers and others who take an interest in public pleasure-grounds, a convention was held at Louisville, Kentucky, on the 20th and 21st of May, at which many interesting papers were read, and, after a full discussion, a society was formed, to be known as the Park and Outdoor Art Association. The following officers of the permanent organization were elected: President, J. B. Castleman, of Louisville, Kentucky; Vice-President, L. E. Holden, of Cleveland, Ohio; Secretary and Treasurer, Warren H. Manning, of Brookline, Massachusetts. The membership fee was fixed at \$2.00 a year, and all persons who desire the advancement of art out-of-doors, including land-owners, park officers, village improvement societies and the like, are invited to unite with the association.

Excepting Lima beans and sugar corn, all the summer vegetables are now in the New York markets, and sweet and white potatoes are almost the only old-crop vegetables still offered. Beets, asparagus and peas all come from fields as near by as New Jersey and Long Island, besides radishes and rhubarb. String-beans and cucumbers come from Georgia and South Carolina, and eggplants, squashes, tomatoes and celery from Florida. Cabbage is coming from Virginia in large quantities. Other vegetables in season are new kohlrabi, carrots, turnips, cauliflower, celeriac, okra and peppers, and onions from Louisiana, Egypt and Bermuda. Vegetables for "greens" and for soups, salads and sauces are offered in almost endless variety, as beet-tops, spinach, sorrel, young celery, parsley, chives, taragon, mint, tansy, dandelion, cress, lettuce and endive. Mushrooms continue plentiful, and sell for fifty cents a pound.

*The Orchid Review* gives an account of some interesting observations which have been recently made at Kew by Mr. Griessen, who has charge of the Orchid-house there. He caught a bumblebee with three different kinds of pollinia attached to it. Between the eyes were two pairs from some *Odontoglossum*, on the middle of the thorax four pollinia of a *Cattleya*, and on the back of the thorax between the wings, those of some *Vanda*, which proves that the bee fed among various species. Another interesting example was that of a common bluebottle fly with the pollinia of a *Cirrhopetalum* affixed to the middle of its thorax. The flower had evidently attracted the insect by its foetid odor. Professor Rolfe gives other examples which have been witnessed, and he well remarks that here is an interesting field of inquiry for all who have an opportunity of observing the fertilization of Orchids in their native homes.

Professor Trelease invites the attention of botanists to the facilities afforded for research at the Missouri Botanical Garden. A large number of native and exotic species and horticultural varieties are grown in the garden, the arboretum and the adjoining park, and the native flora accessible from St. Louis is large and varied. The herbarium includes 250,000 specimens, representing the vegetable life of Europe and America, and it is supplemented by a collection of woods, including veneer transparencies and slides for the microscope. The library

contains 12,000 volumes, 13,000 pamphlets and a complete authors' catalogue. These facilities are at the disposal of professors of botany and others competent to carry on research work of value in botany or horticulture, subject only to such restrictions as are necessary to protect the property of the garden from injury and loss. Persons who wish to make use of them are invited to correspond with the Director, outlining, as far as possible, the work they wish to do, and giving notice, so that provision may be made for the study of special subjects.

Mr. L. F. Kinney, Horticulturist of the Rhode Island Experiment Station, has been observing the Loganberry, which was described with some fullness nearly three years ago (vol. vii., p. 466) in this journal. In an interesting bulletin just issued on the subject, Mr. Kinney publishes a letter from Judge J. H. Logan, of Santa Cruz, California, who planted the seed from which it originated in 1881. The letter gives an interesting account of the plant, which is supposed to be a hybrid between a variety of the European Raspberry and a variety of the wild Blackberry of the Pacific coast. It has been called the Red Blackberry, and the fruit, which is shaped like that of a Blackberry, has a slight but distinct raspberry flavor. The fruit ripens in Rhode Island a trifle later than raspberries and lasts a little longer. It is not highly flavored, but is admirable when cooked, and as a sauce fruit it excels both the blackberry and the raspberry. As the canes trail on the ground naturally some provision must be made for keeping the fruit clean, and it seems to succeed well on a trellis of galvanized iron wire. The trailing and flexible texture of the Loganberry canes makes it easy to cover them, a process which is perhaps advisable in all localities north of this city, for instance, where it might winter-kill. The plant is propagated by stolons, although the seeds germinate readily. Unfortunately, however, the seedlings are comparatively worthless when grown for fruit. Altogether, the Loganberry is the most promising of the new types of small fruit that have been introduced within recent years.

Steamer baskets in the fancy-fruit stores, made up for travelers, are showy with a wide variety of the smaller fruits. One observed on Saturday contained rough-skinned Siam oranges, peaches, Black Hamburg and Almeria grapes, the latter a special favorite with voyagers, California cherries, pears and bright Northern Spy apples. Even so early in the season many of the summer fruits are represented in the fruit stores and markets, although some are yet far from being at their best. Peento, Honey Sweet and Bidwell peaches are coming from Florida, and the first Hale peaches, from Georgia. Other Florida shipments are muskmelons and watermelons. Wild Goose plums, from Georgia, are offered, and blackberries and huckleberries from North Carolina. Green gooseberries come from Maryland. The first North Carolina cherries were seen here on Saturday, but did not rival the large and firm California fruit. The strawberry season is at its height, although there is no ripe fruit from this state. The North Carolina season has passed and the best berries are from Maryland, Delaware and New Jersey. Prices range from ten cents for berries of fair quality to thirty cents for a quart box of large, firm, bright, highly flavored fruit of choice varieties. Some Pringle apricots, from California, were seen here last week, small, and with no value beyond their rarity at this time of year. Valencia seedling oranges, from California, the choicest oranges now in season, cost seventy-five cents a dozen. They are juicy, of excellent flavor and almost seedless. The last Easter Beurre pears cost \$1.00 to \$1.50 a dozen, and the long-keeping P. Barry bring the same price. Above 100,000 bunches of bananas reached this port last week; this fruit is low-priced and is fully grown and of rich flavor. Pineapples are also abundant and cheap, and are coming from the Bahamas, Cuba and Florida. The small sort known as Red Spanish, while less handsome, is preferred by some good judges for its superior quality. These cost from fifteen to forty cents each. Abacca pineapples, of larger size, sell for fifty cents each, and Victoria, the extremely large long fruit, often called Porto Rico, bring \$1.00 each. Among the most costly offerings are hothouse grapes, which sell for \$2.50 a pound. These are seen in unusual variety, including Black Hamburg, the White Muscat of Alexandria, the amber-colored, musky-flavored Muscat of Hamburg, and Dacon Supert with berries round and of clear pale green, unless fully ripe, when they have a yellowish tint. A novelty for dinners and luncheons, designed by one of the uptown fruiterers, is hothouse peaches, each fruit set in a little nest with a dainty paper lining, and marked with the name of the guest in blue and gold.

## GARDEN AND FOREST.

PUBLISHED WEEKLY BY

THE GARDEN AND FOREST PUBLISHING CO.

OFFICE: TRIBUNE BUILDING, NEW YORK.

Conducted by . . . . . Professor C. S. SARGENT.

ENTERED AS SECOND-CLASS MATTER AT THE POST-OFFICE AT NEW YORK, N. Y.

NEW YORK, WEDNESDAY, JUNE 9, 1897.

## The Latest Forest Legislation.

LAST week the National House of Representatives adopted the report of the Conference Committee appointed to adjust the differences of opinion between the two Houses of Congress respecting the forest reservation amendment which had been mounted as a rider on the Sundry Civil Bill. As we understand the situation now, President Cleveland's proclamation of February 22d is suspended for nine months so far as it relates to eleven of the thirteen forest reservations set apart by executive order, and is only operative in the two which are situated in California. This action was, no doubt, taken because it was urged that time was needed to give settlers within the boundaries of the proposed reserves or near them an opportunity to perfect their titles, but its practical operation will be to give the great mining and lumber companies opportunity to get hold of all the timber they need so that they can continue as they have done to get their forest supplies from land that belongs to the people. It is also an advertisement for everybody else to rush in and seize all they can get hold of, after which, in the language of the amendment, "lands embraced in such reservations not otherwise disposed of before March 1st, 1898, shall again become subject to the operations of the proclamation." This means that the state forest lands will be given over to spoliation and speculation, as far as practicable, until that date, when, unless Congress passes some worse law at the next session, the remnants of the forests within these eleven reserves will be again withdrawn from sale and entry. The amendment embraces many other features, such as providing for certain surveys, empowering the Secretary of the Interior to sell timber off of all the reservations, old and new, to issue permits which will enable miners, prospectors and residents to take what timber they need. Prospecting, road-building and selling of agricultural lands are also authorized. Of course, it is a violation of the first principles of safe legislation to add to an appropriation bill such an important and complicated measure as this. Besides setting aside President Cleveland's action, it clothes the Secretary of the Interior with power to establish a system of forest administration in the old reservations, and a system based on questionable principles, to say the least, and gives him no funds to carry it out.

And all this was done without any consideration of the report of the committee of the National Academy of Sciences which had been employed by the Government to examine the subject and give such counsel as the facts in their judgment warranted.

This report was presented to the Secretary of the Interior on the 1st of May, and a limited edition has just been issued. The report proper is comprised within thirty pages, but it is long enough to furnish ample data for the justification of all its conclusions. It assumes, and very properly emphasizes, the fact not generally acknowledged, that the forests on the public domain do not belong to the public-land states, nor do they belong to any one section; moreover, they do not belong to any class—that is, they do not belong to foreign shepherders, who drive their flocks wherever there is a blade of grass or a tender shoot of shrub or tree; they do not belong to prospectors or miners; they do not belong to lumbermen. They are a part of the national heritage, and they are the property of the whole country, of the east as well as the west, and their destruction would mean the paralysis of all our industries and would strike a blow at the agriculture and commerce of the entire land. It is the duty, therefore, of the national legislature to take measures for protecting them. No one's rights are invaded when shepherders are prevented from exterminating the forests, and prospectors are punished for firing forests, either willfully or carelessly, because the entire community is interested in them. How much this great national resource suffers from nomadic sheep husbandry the report sets forth in vivid language. It is shown that these "hoofed locusts" not only render permanent forests impossible by the obliteration of all young growth, but they increase the number of fires, because the herders, after destroying every green thing, even on the most inaccessible slopes of high mountains, set fire to the dry rubbish in autumn when they descend to the plains to stimulate the growth of herbage for another year. And fires in the dry western forests, kindled by careless or ignorant prospectors or herders, have wrought devastation that no one can appreciate without a personal examination. There are no statistics to show how great is the area of timber burned up every year, but the committee report that while traveling for six weeks through northern Montana, Idaho and Washington and Oregon they were constantly enveloped in the smoke of forest fires. Of course, the country suffers enormous loss this way, because these conflagrations once under way among coniferous trees are never stopped until they are put out by a heavy rainfall or encounter a large river. No human agency can check one of these fires after it has begun to run, and the only hope of saving the woods from destruction is by preventing them or extinguishing them at the beginning.

And this leads to the second important proposition of the report, which is that any attempts to protect the forest either from pillage or from the ravages of flocks or of fire have always failed under the ordinary political agencies of the Interior Department. A constantly shifting service with no esprit de corps, no opportunity for promotion, no permanence of tenure, selected as it usually is on the recommendation of men who are in sympathy with those who prey upon the woods rather than with those who wish to protect them, has never shown any efficiency, and, of course, it never will. On the other hand, the experience gained in managing the national parks proves that they can be protected from pillage and from fire, even in the wildest portions of the public domain, by a small body of troops. As a temporary protection, therefore, against depredation and loss, the army, and the army alone, will prove efficient. The committee therefore recommends that each important reserve should be placed at once in charge of an officer of the army, detailed during the season when forest fires are to be dreaded, to report to the Secretary of the Interior and act as superintendent, and that he should be supported by sufficient details of soldiers. Of course, this is not to bring in a revenue, nor yet to establish a system

of forestry; it is simply to save the woods from the lawless depredations of men and animals and the terrible dangers by fire.

But this is only a temporary expedient to bridge over the time until there can be a permanent organization. The management of forests requires such a wide technical knowledge, and such a sustained effort to be persisted in through generations, that success is possible only through an organization as stable as that of the army or the navy. And this seems to us the most important feature of the entire report. It is hopeless to expect that forests can be preserved, much less managed for production, under any form of civil service that now exists. A regularly organized forest bureau, consisting of officers of the highest personal character and of liberal scientific education, is needed, and men of this class cannot be had unless their tenure of office is permanent and their remuneration is liberal. As the committee point out, however, it is no unusual occurrence for a single fire to destroy in a few days material which is worth more in actual money than such a forest administration would cost in years, while the loss to the country in impaired waterflow, through forest fires which might easily be prevented by such a service, is incalculable. The expenditure, therefore, of as much as \$250,000 a year, the sum indicated by the commission as necessary to furnish means for protecting the forests on the public domain, is justified by every consideration of common sense and of economy.

We have no space to speak of the chapter on the unreserved forest lands of the public domain, or of the proposed Board of Forest Lands, which is charged with the decision of certain very important questions. We will only add that one of the bills published as an appendix to the report provides that all public lands of the United States which in the judgment of this Board are more valuable for the production of timber than for agriculture or mining shall be withdrawn from sale, settlement and other disposition, and held for the growth and sale of timber. Other bills provide that the upper slopes of Mount Ranier, with its glaciers and alpine meadows, and the marvelous Grand Cañon of the Colorado in Arizona shall be preserved without any further defacement than is necessary to make them easily accessible to the people, and that they therefore should be set aside and governed as national parks.

No one can see far into the future, but it looks as if Congress had taken effective means to postpone all attempts at the efficient protection of our forests and to prevent the adoption of the conservative measures recommended by the committee of the National Academy of Sciences.

#### Plan of a Country Place in Connecticut.

EVERY piece of land, especially in the older portions of our country where the forces of nature and the hand of man have been at work to mould and develop its particular features, has a character of its own. This character may be pleasing, and, if so, when the land falls under the control of the landscape-gardener it is always best for him to work in harmony with the spirit of the place so as to emphasize and bring out its special beauties rather than to struggle against nature and attempt to transform it into something essentially different. The plan on page 227 shows a design for home grounds in which the aim has been to preserve the original features and make the most of them. The property had been for years a New England farm of the better class, and little attention had been given to matters that were not strictly utilitarian. Nevertheless, there were plain advantages in its elevated situation, and the consequent breadth of view afforded, in its varied ground surface and its fine natural growth of trees in groups or isolated specimens. Altogether, these well-disposed Oaks, Ashes, Maples and Elms on the rolling surfaces give a dignified air to the place, with occasional picturesque passages, and the design has been elaborated along these lines. The aim has been to unite the scattered elements

of value and so to dispose the architectural features in relation to them as to make a harmonious effect.

The house is situated on high ground with a fine background of large trees, and plantings have been added as required to screen but not to entirely conceal the green-houses and stables and minor buildings. Since the ground falls rapidly from the back of the house to a level fifteen feet lower—a level which is maintained in the adjoining meadow-land—these accessory buildings are properly subordinated. Being on level ground they are mostly connected by straight roads. In front and at either side of the house the ground slopes gradually, the street level in front being five feet below it. The approach-drive entering with a descending grade quickly passes through masses of trees, after which a broad expanse of undulating lawn comes into view, and the bordering plantations suggest its continuance beyond by the farthestmost groups of trees. It then enters a closely planted copse from which the grade ascends continuously to the house. The house is visible on emerging from this planting, and is here seen to good advantage with fine stretches of lawn in front and on either side, with a heavy background of trees supporting groups to the left, an incidental glimpse of a little garden behind some bordering shrubbery, and views on the lower grounds to the right. Fine prospects open from the house. On one side the well-kept lawn comes close to the foundation, and the two are united by shrubs and vines; on the other is a foreground of pasture-lands with wooded hills beyond the railroad, the glittering waters of the Sound in the offing, and on clear days glimpses of Long Island in the distance. The screen which hides the railroad is of such moderate height that it will not obstruct the distant prospect. Continuing past the house the drive begins to descend, and opposite the end of the greenhouse it enters a winding valley. Following the low ground a pleasing succession of concave surfaces comes and goes until a close-growing piece of natural woods is reached. From this point to a ledge of rock near the exit is a steep hillside on the left, which ascends to the street some fifteen feet above it. The road first passes through the dense shade of overhanging trees, then skirts a small opening with the half-concealed ledge at the farther end. This ledge makes an appropriate finale to a drive which in its course has brought to view a succession of interesting scenes, all of them united in that they suggest throughout the main idea. The numerous curves suit the grounds, and there is an evident reason for every one. The plantations have been disposed so as to help the architecture where they are related to it and unite the scattered trees which originally existed, while simplicity and breadth of effect has been the aim at every point.

The material for planting has been selected with a view to preserve the quiet dignity of the place. Near the house trees like the Yellow-wood, Beech, American Hornbeam, Liquidamber, Magnolias and a few *Koelreuterias* have been selected; while further away Oaks, Chestnuts, Maples, Elms, Ashes and Lindens are used, and on the natural wood-borders Flowering Dogwood, the Judas-tree and Thorns in variety have been used, with many woodland Ferns, flowers and shrubs. Among the latter *Rhododendron maximum* has been very freely planted. Along the low ground bordering the railroad an effect such as is often seen in New England in the richer lowlands has been attempted, especially in regard to the autumn foliage, by planting Swamp Maples, Sumachs in variety, *Amelanchiers*, Cornuses, *Viburnums*, *Celastrus*, some White Birches and White Pines. In this scheme the general character of the place can be seen at once, although there are certain details of the work which can only be brought about gradually, owing to the undesirable position of some of the old trees and the lines of former roadways. Nevertheless, with the hearty coöperation of the architect and the intelligent interest of the owner, the successful development of the design seems assured.

New York.

Charles H. Lowrie.

## The Flora of Ukiah Valley.

IN a former article (vol. ix., page 482) I touched upon the geological formation of Ukiah Valley, and stated that Ukiah Valley was once a lake, not in the distant past, but so recently that its extinction cannot date back more than a hundred years. Nearly all of the oblong or round valleys, common in the Coast Range north of San Francisco Bay, are also the beds of lakes. Northward of Ukiah several valleys on Eel River still contain the remnants of the lakes at the lower end. East of Ukiah lies Clear Lake, quite a large body of water, and at its north end Sule Lake is a vivid illustration of the process by which so many other lakes have been extinguished. This is a lake of considerable size, so much shoaled by deposits that tall rushes cover nearly the entire surface, and inpouring streams are rapidly filling it on the sides. Such a lake once covered Ukiah Valley. Swift-coursing streams poured from the steep mountains about and carried great quantities of débris. The prevailing formation is sandstone and shale, which rapidly disintegrates, and the slopes are so steep that erosion is rapid. Deltas of gravel or clay were formed where the streams deployed into the valley. Those formed when the lake was highest are the high bench lands about the bases of the mountains. Lower benches were formed in succession as the lake receded, and when at last the valley was drained by the combined process of filling on one hand, and the cutting down of the outlet on the other, the larger streams cut through their earlier formation, making rich vales, while the smaller streams deployed over the mud flats and carried rich deposits of mud, fine gravel and leaves to form the black gravel lands of to-day. This latter process is rapidly going on even now. At the final ending of the lake the extinction of the beaver and the burning of their dams bore no small part. Along the large streams alluvial deposits were made, gradually raising the land next them to a little above the height of the lower valley between the rivers and the benches.

In our beautiful valley each formation has its flora. The trees and shrubs on the higher benches vary according to the soil. Most of the benches were in woods, especially where the formation was a deep gravelly one. Some extensive benches were formed by the large creeks rising in the Chemise-covered mountains. These are a very deep poor gravel, and are a home for nearly all of the trees and shrubs and many of the plants characteristic of the Chemise region. More frequently, however, the uplands were clothed with a fine growth of timber, among which the Black Oak, the Post Oak (*Quercus Douglasii*), the Douglas Spruce and the Madroña predominated. There were large trees in abundance and a wealth of flowers beneath. Since I have known these uplands there has been an undergrowth of young Madroñas, both seedlings and clumps of sprouts from older stubs, of Manzanita and of Oaks. The Douglas Spruce, too, are mostly young trees. I have no doubt that previous to the settlement by the whites almost annual grass fires, set by Indians, kept this small growth down, and that the woods then were quite open. Along the river banks, and covering almost the entire alluvial deposit, was another strip of woodland which has now largely given way to orchards, Hop fields and Alfalfa. Sections still remain thickly clothed with White Oaks, *Quercus lobata*, Ash, Laurel, Willows, which are not bushes, but large trees, Box Elder and Cottonwood. Occasional Alders, brought down by the streams from their mountain home, live next the water, and nearer the hills, too, the Oregon Maple. *Clematis ligusticifolia* and wild Grapes climb to the tops of great trees. Wild Blackberries run riot over bushes, and in early summer the Big Root, *Megarrhiza* Marah, grows as luxuriantly as the famous Bean-stalk in Jack's romance, for a short while, and hangs thick with its thorny-looking fruits. Here are thickets of wild Roses, *Rosa Californica*, ten or twelve feet high. Down in the river bed the deposits of sand or gravel harbor many plants of mountain origin, which in their short existence rival their

home brethren. Some of these river beds are a rich field for the flower lover. Late in summer they have their own flora, such as the gorgeous *Mentzelia laevicaulis* with rich yellow flowers fully six inches across.

The lands lying between the alluvial belt and the first bench are low and often wet. Few trees grow on them, except scattering White Oaks. Originally they were covered by a dense growth of Grasses and wild Anise, with a multitude of flowering plants, many of them liliaceous. The rich, gravelly deposits were the favorite home of the White Oak, and before the needs of the farmer caused these to be cut they formed open woods for miles in the valley, and nearly all were large trees. In such grounds, too, the Elder is to be found, not the bush of the eastern states, but a tree a foot or more in diameter and twenty or thirty feet high.

The flowers and trees of the lower hillsides vary as the soil differs. Those facing south are oftener bare or thinly timbered, and those facing north are usually well wooded. In my article, "A Cañon near Ukiah" (vol. ix., p. 482 and p. 493), I described a prevalent form of growth. The cañons on the east side of the valley differ from those on the west, as I hope to show another time.

Ukiah, Calif.

Carl Purdy.

## Foreign Correspondence.

## London Letter.

*ARISTOLOCHIA GOLDIEANA*.—Plants of this extraordinary Birthwort have lately flowered in the stoves at Kew. It is a native of Old Calabar, where it occurs abundantly in swampy ground, the large flowers resting on the earth and impregnating the air with their fetid odor for miles around. It has been in cultivation about thirty years, but from the difficulty of inducing it to flower it has never found any favor outside botanic gardens. It differs from the popular, easily grown *Aristolochia Gigas Sturtevantii* in having a tuberous root-stock, annual stems, and in the flowers developing on the base of the young growth before the leaves have appeared. During winter the plants should be kept quite dry, and in March they should be saturated with water and placed in the hottest, moistest, sunniest position in the stove. The flowers are twenty-six inches long, a foot in diameter, three-lobed and colored chocolate-red with yellow mottlings.

*SOLANUM WENDLANDII*.—This plant is again magnificent in the Water-lily house at Kew, where it festoons a portion of the roof with its straggling stems, bearing enormous clusters of bright purple-blue flowers. Nothing could be handsomer in the way of a roof-climber for the stove, and no plant gives less trouble to the cultivator when once its requirements are understood. For years it was grown in a pot among the Succulents at Kew, treatment which kept it alive, but never induced it to flower. It was then planted in a shallow border in the porch of the Water-lily house and the shoots trained along the girders of the roof. The bright sunshine and fresh air which it here obtained suited it, and it has flowered freely and continuously every year since. During winter it is kept quite dry when all the leaves fall off. In February it is pruned to short spurs; the roots are then well soaked with water and top-dressed with manure. These details may help those cultivators who have tried and failed with this grand plant.

*UTRICULARIA FORGETIANA*.—This is the name given by Messrs. F. Sander & Co. to an exceptionally strong-growing, large-flowered variety of the Brazilian *Utricularia longifolia*, which they have recently imported and which has flowered freely this spring in their nursery. The stems creep as in the well-known *U. montana*, and from them spring numerous linear lanceolate wavy leaves about a foot long. The flower-spikes are erect, two feet or more high, each bearing from twelve to twenty flowers, which are two inches across and of a rich violet-blue color with a blotch of orange-yellow on the boss-like cushion at the base of the lip. The flowers last about a week, and Messrs. Sander & Co. have had plants continuously in bloom for

over two months. The introduction of this and other giant *Utricularias* from South America is very creditable to the St. Albans firm, for they are plants of greater interest to botanists than to horticulturists, the latter finding them difficult to manage. From what I hear *U. Forgetiana* is as easily grown as *U. montana*.

**BOWENIA SPECTABILIS.**—Hitherto this remarkable Cycad has found no favor with the ordinary cultivator, but Messrs. Sander & Co. have succeeded in raising a large number of seedlings of it, and these reveal the merits of the plant for purposes of decoration. The root-stock is a fleshy tuber from which rise numerous decompound leaves resembling the fronds of a gigantic *Adiantum*. Large plants produce leaves a yard in diameter, and as the leaflets are elegant in form and of a rich glossy green color they are decidedly ornamental. Small plants have leaves of various sizes, and are especially adapted for vases, drawing-rooms and all purposes of ornamentation, the uncommon structure of the fronds—indeed, one may say of the whole plant—being of a character likely to excite interest as well as admiration. The plant is monotypic and is a native of Queensland.

**PHAJUS CALLOSUS.**—An importation of this Orchid was sold at the auction-rooms this week by Messrs. F. Sander & Co., who collected the plants in Perak. It is very similar to *Phajus Wallichii*, but is easily distinguished from that species by its more oblong sepals and the broad ends of the petals, while the lip has a tubular limb and short midlobe, the spur being short and incurved. Their color is dull reddish brown, the lip yellowish white, tinged with pink, bright red toward the apex. The color of the flowers varies considerably with age. A plant of this species flowered in the Kew collection last year, but it is rare in cultivation. It is a native of Java as well as the Straits Settlements. *P. Mishmensis*, from the Mishmi Hills, in Upper Assam, a species with rose-colored flowers, is worth the attention of collectors. It flowered recently at Kew, and a figure of it was published in *The Botanical Magazine*, t. 7479.

**OXALIS ENNEAPHYLLA.**—This is a most distinct and charming species of *Oxalis* which is hardy at Kew, where some plants of it are now flowering freely in a shady nook in the rock garden; there are also about a dozen pots of it in flower in the alpine house. It has fleshy thinly ovate bulbs an inch long, and tufts of short-stalked leaves which are very glaucous, and the blade is divided into from nine to twelve linear, overlapping pinnae. The flowers are among the largest in the genus, being over an inch in diameter, the petals of solid substance and pure white. It is a native of the Falkland Islands, whence it was first introduced by the late Professor Moseby during the Challenger Expedition in 1876. The large batch of plants now in flower at Kew were collected in the Falklands by Mr. Linney, the Governor's gardener, formerly employed at Kew. It is there known as "White Lady." This is the only species of *Oxalis* known to me that requires a shady position.

**CAMPANULA PERSICIFOLIA.**—Some of the varieties of this handsome *Campanula* are most useful for pot-culture for the conservatory. They force freely; indeed, with good cultivation and the application of a little heat, they produce finer flowers than when grown in a border out-of-doors. The best of them all is one called *Alba grandiflora*, of which there are now numerous examples in the conservatory at Kew. They are two feet high, clothed with large bells two inches in diameter and of the purest snow-white; they have been in flower since the beginning of May. These plants are grown in pots in the open air all summer and wintered in a cold frame. In February they are placed in a sunny greenhouse along with Zonal *Pelargoniums*, where they soon push up their flower-stems. The varieties come true from seeds. There are other white-flowered forms, but that here named is the largest and best of those tried at Kew.

**PELARGONIUMS**—I do not gather from W. S. A.'s interesting paper on *Pelargoniums* at Cornell University (page 184)

that he is acquainted with Sweets' *Geraniaceæ*, which contains excellent colored pictures and descriptions of hundreds of *Pelargoniums*—species, hybrids and seedlings. The efforts of modern breeders of these plants are limited to the three races—Zonal, Show and Ivy-leaved—but any one familiar with the species of *Pelargonium* found in south Africa will know how great is the variety and how interesting the characteristics of many of them. There is a fairly comprehensive collection of these species in cultivation at Kew, where their peculiarities are a source of interest to visitors who know the ordinary types, but are fain to believe that they have any close relationship with these "queer-looking" and, in some cases, distinctly pretty plants. We owe many of these to Philip Masson, who collected for Kew in south Africa a hundred and twenty years ago.

## Entomological.

### The Pistol-Case-Bearer.

THE interesting insect which is shown in the accompanying illustrations is evidently becoming one of the serious insect enemies of the Apple orchards in this state. Last year we received many complaints from prominent fruit growers from various sections of the state, and especially from those residing in the more important apple-growing counties of western New York. Judging from letters received and from our own observations, there are as many or more of the case-bearers this year than last. Some of the large orchards near Geneva are badly infested, while many of those about Rochester and westward, in the vicinity of Albion and Lockport, appear to be even more seriously attacked. The nature of the insect is indicated in the illustrations. It is one of the case-bearing species, and as the case which each caterpillar constructs slightly resembles an old-fashioned pistol in shape, it is commonly known as the pistol-case-bearer. Its scientific name is *Coleophora malivorella*. It was so named in 1878 by Dr. Riley, who published a technical description of the male and female moths in the Report of the United States Department of Agriculture for that year.

The case is for the protection of the insect while in the larva and pupa stages. During the winter the cases may be found attached in a nearly upright position on the bark

Fig. 28.—Young Pistol-case-bearer, natural size, on an Apple leaf-bud.

of the smaller twigs, and usually near or even upon the buds. They measure on an average about an eighth of an inch in length. With the first warm days of spring the little case-bearers become active and make at once for the nearest buds, carrying, as it appears, their odd-looking cases on their backs. They bore into the swelling buds to

feed on the tender tissues. Fig. 1 is from a photograph made April 24th, showing a pistol-case-bearer, of natural size, at work on an opening Apple-leaf bud. After the photograph was made the case-bearer was removed, showing a small round hole just large enough to admit the insect's

the leaves have become well expanded the case-bearers attack these also, eating away the soft parts at first, but finally eating holes clear through them. Later in the season, when they have become larger and stronger, they readily devour nearly the whole leaf with the exception of the midrib and larger veins.

Although the case-bearers do serious injury in thus feeding on the leaves, they probably do as much or more harm by attacking the opening flower-buds and the fully expanded flowers themselves. They feed on the interior of the flower-buds, eating away the tender tissues, destroying the life of the buds and thus preventing the development of the fruit. In the same way the flowers are destroyed, both the petals and essential organs being devoured. The fruit is also sometimes attacked, the case-bearers boring through the skin and feeding on the tissues just beneath. This causes the apple to become more or less deformed, according to the extent of the injury. Young pears also suffer in this way.

During the middle or latter part of May the case-bearers are ready to pupate, and accordingly migrate to the twigs, where each larva attaches its case firmly and in a nearly upright position to the bark. They then manage to turn around in their cases so as to bring the head in the opposite direction from its original one. While in this position the change to the pupa takes place. About the middle of June the mature insects, small gray moths, come forth, making their exit by means of a slit in the upper end of the case. Egg-laying soon begins, the eggs being deposited on the under side of the leaves. As soon as hatched, the young case-bearers begin to construct their cases, making them of excrement and silk, and begin to eat small round holes into the interior of the leaf. Before winter sets in they migrate to the twigs, where their cases are firmly attached to the bark in a nearly upright position, to remain until spring comes again.

This is in brief the life-history of this interesting insect. We have discussed it more in detail in Bulletin No. 122 of this station. Although apparently so well protected, many of the case-bearers succumb to the attacks of parasites. We have bred three species from insects kept in the laboratory.

As to remedial measures, theoretically the case-bearers can be controlled by spraying the trees with Paris green just before the leaf-buds begin to swell, so that the first meal of the newly awakened insect will be a poisoned one. Our experiments last year showed that an application of Paris green made at this time, using one pound to 150 gallons of water, aided materially in holding the pest in check.

Two applications of the poison were made later in the season, however, one just as the young case-bearers were observed eating holes clear through the leaves, and another soon after the petals had fallen. These three applications proved successful in keeping a number of Apple-trees which had been badly infested comparatively free.

Although apparently preferring the Apple, this case-bearer attacks the Pear and Quince.

A closely allied species is the cigar-case-bearer, which has many similar habits, but which can be readily distinguished from the shape of its case.

New York Agric'l Experiment Station, Geneva, N. Y.

V. H. Lowe.

Fig. 29.—Young Pistol-case-bearer on opening leaf-bud of an Apple, enlarged nearly five decimeters.

body. This hole reached well toward the interior of the bud, where a cavity was evidently being made in consequence of the devouring little insect's appetite. While feeding in this way the caterpillar did not lose hold of its protecting case, but apparently held it in position by the posterior segments of its body. It does not appear to be the habit of the caterpillar to leave its case, but to thrust its body out as far as possible without losing hold of this protecting retreat.

Fig. 2 is from a photograph made April 29th and shows the insect enlarged about four times. It will be noticed that the case is not quite the same shape as the one shown in Fig. 1. As the case-bearers enlarge they change the shape of their cases slightly, and also lengthen them as the increasing size of their bodies demands. When of full size they measure about one-fourth of an inch in length. The twig in the figure was cut from a three-year-old Apple-tree in the nursery row. The case-bearer was working on the interior of the bud at the base of the opening leaves. When

## Cultural Department.

### Choice Hardy Plants.

IN a slightly shaded, cool, moist and sheltered position a bed of *Gentiana acaulis* is now freely showing its beautiful flowers. The bright dark blue flowers are large, considering the size of the plants. They are campanulate, but not droop-

ing, two inches long, and are borne singly on upright stems three or four inches high. This choice alpine plant is quite noticeable, even when not in blossom, on account of its bright green shining leaves which nestle close to the ground in rosettes. A deep light loam with a bit of limestone will suit this plant.

*Primula Japonica* is a desirable plant for the rock garden, and it is not generally known that it will withstand the most severe winters here. It will even ripen seeds freely, and if these are not collected they are scattered about the old plants, where they germinate and become healthy seedlings. Here *P. Japonica* thrives in a slightly damp, deep, rich soil, and is now throwing up flower-stems to a height of a foot and a half. The crimson flowers are produced in whorls along the stems, and as they do not all open at the same time, the flowering season is much lengthened. My experience with the seeds is that they germinate about a year from the time of sowing.

Another Japanese Primrose blossoming now is the lovely *Primula Sieboldii*, one of the most floriferous and showy of all the Primroses. We have extra-strong healthy plants, which keep on increasing every year. The flowers, an inch and a half in diameter, are produced in umbels of eight or ten on stems about a foot long. This deciduous species, if grown in a warm sheltered place and covered over with leaves in winter, proves quite hardy. A slightly moist, rich, loose soil suits the plants here, and in a somewhat shaded place the flowers last longer.

For the front row of the mixed border, or for slightly elevated parts of the rock garden, *Aster alpinus* is deserving of notice at this time. It is an attractive species with a dwarf, stout habit, and grows vigorously here. The bright purple flower-heads are produced singly on stout stems which rise six or nine inches, and they measure two inches in diameter. This *Aster* can be increased easily by division and is readily raised from seed.

The native leguminous plant, *Thermopsis mollis*, should be in all gardens, and is an excellent perennial for the border. It has a stout, bushy habit and needs no staking to keep it in position. It flourishes in deep rich soil in an open position. This plant is about three feet high and its stems have palmately three-foliate leaves. The flowers are yellow and are borne in long terminal racemes, which last in good condition for a considerable length of time. The seeds are sometimes slow to germinate, and show no sign for more than a year after they are sown.

The horned Pansy, *Viola cornuta*, is valuable for its continuous blooming qualities. In a cool, shaded spot it flowers all summer. The flowers are pale blue and of good size. A variety of this species, *Perfection*, is a desirable plant, having a dwarf habit and abundant blue flowers as large as an ordinary-sized Pansy. *Violas* are easily grown and flower profusely during the hot weather and deserve a prominent place in our borders.

*Calamintha alpina*, a hardy plant from the south of Europe, is one mass of small blue labiate flowers. It is a valuable plant for the rock garden, and also grows freely in any ordinary good garden soil. It is a low-tufted plant, about six inches in height.

The large patches of *Stellaria holostea* are now out of blossom, and in the borders the *Cerastiums* are the most prominent low-growing plants, with white flowers. *C. arvense grandiflorum* is remarkably good, with large white flowers. *C. Boissieri* is a distinct species, with silvery foliage and medium-sized white flowers. It is quite hardy here and grows vigorously, while *C. tomentosum*, another species with silvery leaves, does not stand the winter well with us. Other species in bloom now are *C. oblongifolium*, *C. arvense*, *C. dichotomum* and *C. alpinum Fischerianum*. The double form of the rich yellow-flowered *Ranunculus acris*, commonly called Bachelor's Buttons, is a profuse bloomer in a slightly damp and cool place.

In the rock garden *Silene alpestris* has proved quite hardy and is a choice plant for a slightly elevated position. It has panicles of pleasing white shining flowers and a dwarf compact habit. This native of the Austrian Alps was introduced more than a century ago. Another choice species with much the same habit and requiring the same treatment and situation is *S. quadrifida*. *Saponaria ocymoides* is valuable for the drier parts of the rock garden and the front row of a dry sunny border. The prostrate stems of this beautiful trailing plant are almost hidden by its rosy flowers.

The European *Salvia pratensis* is the first species of this large and showy genus to blossom. It makes a good border plant, and its long, graceful racemes of blue flowers are conspicuous now. In the front row of the mixed border patches

of *Veronica rupestris* are decorative. The flowers are pleasing and produced in great abundance. *V. paniculata* is slightly taller than *V. rupestris* and has larger panicles of flowers. Other choice species now blossoming, and all easily cultivated, either in the border or rock garden, are *V. Austriacum*, *V. Tencrimum* and *V. gentianoides*.

Harvard Botanic Garden, Cambridge, Mass.

Robert Cameron.

### May Irises.

**I**RIS BOSNIACÆ, as suggested by Herr Leichtlin last week, is a handsome dwarf species, and it has been described in GARDEN AND FOREST. But the leading idea in these Iris notes has been to call attention only to those which have proved reliable in my garden and are presumably those best adapted to general cultivation. *I. Bosniacæ* has dwindled away twice here, and for this reason was omitted. To my taste *I. cristata*, which was inadvertently overlooked, is the choicest dwarf species of the family. It is very dwarf, indeed, and has beautiful light lavender flowers with fine markings, and generally thrives in the border without special care. Another bright Iris of May is *I. Hookeri*, the Canadian common species, which has very small standards and very bright purple-blue flowers and leaves an inch broad. The Iris of the middle west, *I. Missouriensis*, is also a very gracefully habited plant with linear leaves and small blue-purple flowers of a medium shade, but it scarcely flowers as freely as *I. Sibirica*, nor are its stems as tall. The two best forms of *I. Sibirica* are *I. Sibirica flexulosa*, with white flowers, and *I. Sibirica hæmatophylla* (or *sanguinæa*, from the reddish young leaves and spathes). The latter form is often sold as *I. orientalis*, but this name is properly applied to *I. ochroleuca*, which will be noted among the June Irises. *I. orientalis* is one of the species which are usually sent out incorrectly by dealers. *I. Sibirica* is very common in eastern Asia, and as it seeds freely is often sent home by travelers with provisional names which stick to it.

No collection of May Irises would be complete without two noble plants, *I. pseudacorus* and *I. pallida*, var. *Dalmatica*. The former is a tall-growing kind, thrives well in the border, but is especially attractive in wet places on margins of streams or ponds. The yellow flowers vary in different forms, from yellow to cream color. The Dalmatian Iris is a stately plant which should be isolated where its distinction may be noted. It has very broad short leaves, and the large light purple flowers are carried well above these on tall stems. It is very fragrant with an Elder-like odor.

Elizabeth, N. J.

J. N. Gerard.

### Notes from the Arnold Arboretum.

**S**O numerous are the desirable trees and shrubs in bloom in this well-kept and orderly department of the park system of Boston that it is impossible to give even a list of them. By systematic care, a perfect record and up-to-date nomenclature, this institution is becoming of inestimable value, not alone to Boston, but to the whole country. As soon as established plants are available, representatives of every genus of cultivated shrubs and trees—often by many species and varieties—are planted in order, which is a great convenience to those who desire to study them, for one's interest is certainly increased by the assurance that they are all properly classified and named.

During a visit made a month ago, a thousand or more seedlings of *Azalea Indica*, var. *Kæmpferi*, were in full bloom. These have stood two winters unprotected, and there is no reason why they should not be accounted hardy. These seedlings were part of a lot of ten thousand raised by Jackson Dawson from seeds gathered by Professor Sargent in Japan, and consignments have been made to all the best gardens of England and the continent of Europe. Their earliness is remarkable; they flower ten days before *Azalea mollis*, and more than two weeks earlier than the Ghent *Azaleas*. The *Indica* type are mostly in colors of warm red, orange-red and reddish pink. The markings of the standard petal show their affinity clearly. Here is an opportunity, which undoubtedly will be taken advantage of, to hybridize these with other species and varieties.

The Japan Quince was at its best at the time of my visit, and represented by many peculiarities in habit of growth and color of flower. Some are upright, others prostrate, and the salmon-tinted and white-flowered were exceedingly effective. The Crab-apples, a study of themselves, are seen in several types, which merge into one another. Those of upright habit, with larger leaves, flowers and fruit, known as the *Baccata* group, resemble more nearly our cultivated Apple. The

Toringa and Spectabilis groups we would recognize anywhere as Crab-apples, being more diffuse in habit and exceedingly floriferous. At a later visit I found all the Crab-apples, with the exception of a few American species, past, and of these *Prunus coronaria* is the most noteworthy. It is a tree worth a place in any garden; it is handsome in foliage, and in flower fragrant as a Tea Rose.

The European Lilacs are about past, and a long bank of these in bloom together makes a gorgeous show. Although grouped for comparison rather than effect, the average visitor considers them only from the latter standpoint; and while the landscape-artist may object to such planting, it is invaluable for study and comparison. Among the best varieties I noted *Alba grandiflora*, white; *Dr. Regel*, lavender; *Lagraye*, white; *Virginite*, double blue, fading to white, the most admired in the group; *Massart*, purple; *Notger*, blush; *Leon Simon*, double light blue; *Lemoine's new hybrid*, *Lewis Henry*, has very large blue flowers, in size covering a silver quarter dollar by actual trial. *Concordat* has the largest panicle of any in the group, measuring fourteen inches in length and breadth. The

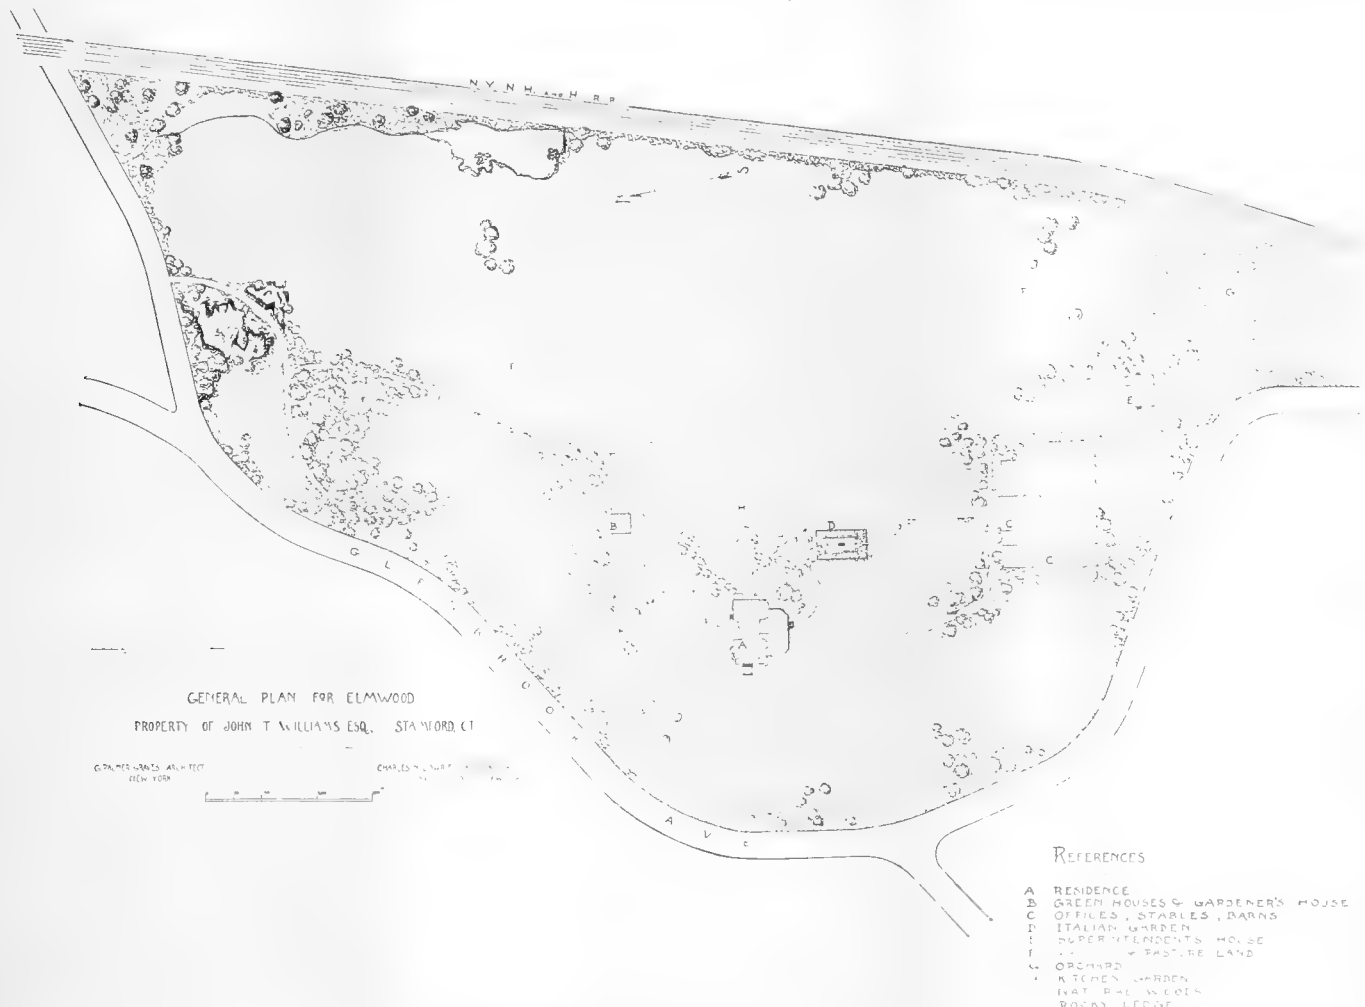

free; *L. media*, dwarf and graceful; *L. vulgare*, the common European Privet, stiff and with dark leaves. This is a common hedge plant in the Old World, but is not nearly as handsome as the Californian *L. ovalifolium*, where this will succeed.

*Cotoneaster reflexa* is very free-flowering. It was a sheet of white and strikingly beautiful. *Caragana arborescens*, the Siberian Pea Tree, is a beautiful shrub or small tree which should be better known. In habit it suggests *Cassia marilandica*, with showy yellow pea-like flowers. There are several kinds, and a weeping form, *C. grandiflora*, is the handsomest.

Shrubby *Spiræas* were plentifully in bloom. *S. arguta*, new, is intermediate in habit and time of blooming between *S. Thunbergii* and *S. Van Houttei*. It makes a handsome bush. *S. pubescens*, from China, is another distinct kind. *S. rotundifolia* is valuable on account of its lateness. *C. cana savanica* has a neat feathery habit. A selection of *Barberries* includes *Berberis Cretica*, with glaucous foliage, an exceedingly dwarf form of *B. Thunbergii*, *B. heteropoda*, fine foliage and large flowers, and some good forms of *B. vulgaris*.

Wellesley, Mass.

T. D. Hatfield.

more distinct Japanese and Chinese species and varieties will not be open until well into June. Of the group, *L. villosa*, purple, fading to white, and very handsome, is the earliest, and is just opening. A noble specimen of the Tree Lilac, *Syringa Japonica*, already nearly thirty feet high, will be worth a visit when it is covered by hundreds of diffuse panicles of creamy white flowers. *L. Pekinensis* also forms a graceful tree.

The Bush Honeysuckles afford much variety. *Lonicera Tartarica* is represented by several forms which differ mostly in the color of their flowers; these vary from creamy white to pure white and clear pink. There are, besides, several distinct species well worthy of cultivation. *L. Morrowi* is a neat bush with gracefully recurving branches clothed with a mass of blush-white flowers. *L. Alberti* has pink flowers and is of prostrate habit; *L. savanica* makes a neat bush. *L. alpigera* has red flowers, and the pretty *L. minutiflora* white and pink flowers.

The Privets form an interesting group, and when in bloom, a week from now, will be a sheet of fragrant white flowers. *Ligustrum Iboti*, a Japan species, is loose-habited and

Native Water-lilies.

**N**YMPHÆA ODORATA, the well-known fragrant Pond Lily of North America, and *N. tuberosa* are the only two *Nymphæas* indigenous to the United States east of the Mississippi, as given by Professor Asa Gray. Of the first species there are many forms, which vary in size and color, and of the latter there are varieties with white and pinkish flowers which range from white to bright pink-red, while in size they range from five inches in diameter downward, according to soil and location. Since the introduction of *Nymphæas* into the flower garden they have become very popular, and many new forms, by hybrids and sports, have been introduced in such variety that no water garden is complete without them. The following list of varieties will show the truth of this statement: *Nymphæa odorata*, white, sweet-scented, large; variety *Caroliniana*, rosy pink, shaded salmon, larger than the type; *Exquisite*, rosy carmine; *Union*, white and small; *Rosea*, the well-known Cape Cod pink Pond Lily, larger than the type; *Rosacæa*, salmon-pink; *Sulphurea*, hybrid, yellow. The

variety sent out as *Gigantea* is a misnomer and does not belong to this species, and the same is true of *Maxima*. The mistake was, doubtless, accidental, but it is vexatious to find valuable varieties disseminated under a wrong name or not in their right class.

*Nymphæa reniformis*, syn. *tuberosa*, is a vigorous species, with leaves prominently ribbed, root-stock bearing numerous, often compound, tubers, which spontaneously detach; the flowers are white, never pinkish, from four and a half to nine inches in diameter, slightly fragrant, indigenous to lakes and slow rivers in western New York, and near Meadville, Pennsylvania, to Michigan, eastern Nebraska, and probably to the southern states.

*Nymphæa tuberosa*—the true species—should never be planted in a pond with other choice, hardy *Nymphæas*. It is a rampant grower, produces seeds very freely, besides multiplying prodigiously from the small tubers, and when established its massive leaves stand out above the water, shading and smothering out all other *Nymphæa* growth. Since its introduction into ponds where other varieties were grown the flowers have been cross-fertilized, and numerous forms and gradations are to be met with. Several of these have value as decorative plants and bid fair to equal the *Odorata* type, if not to surpass it in gradations of size and color. With this I send two varieties of the species. The pink-flowered variety received a certificate of merit from the Massachusetts Horticultural Society three years ago, and was disseminated by me under the name of *N. tuberosa rosea*. The large white-flowered variety originated in Ohio, or is known there as *N. tuberosa*, but it is so entirely distinct that I suggest for it the varietal name of *plena*, to distinguish it from other forms. From the same source I received a variety under the name of *N. odorata superba*, but after careful cultivation I find it to be the true *N. tuberosa*. Another form received under the name of *N. superba* has all the characteristic points of the same species. Yet another variety from the rice fields of Carolina, under the name of *N. odorata gigantea*, was grown alongside of *N. tuberosa*, and no distinction between the two was noticeable. Numerous shades of pink have been noticed in the flowers of *N. tuberosa*, but the variety *Rosea* is thus far the best. All are early-flowering and desirable for special purposes. The greatest confusion exists through the introduction of the many forms of these two species without any proper classification, and it is to be hoped that some botanical society will take the matter up.

Riverton, N. J.

William Tricker.

[The pink flowers sent to this office were of a singularly delicate shade of color, and the white ones were very large and double.—Ed.]

*Lathyrus rotundifolius*.—This seems to be the earliest-flowering of the hardy Peas, beginning to bloom in early May. At this time it has stems six feet long, bearing a profusion of flowers of a deep rosy red color, known sometimes as old rose. This Pea is also known as *Lathyrus Drummondii*, and is highly valued wherever grown, for, next to the white-flowered form of *L. latifolius*, it is probably the most generally satisfactory hardy Pea in cultivation, as the color is a pure tone, which contrasts most pleasingly with the light green leaves. It is perfectly hardy and may be increased from seed or by division.

*Cypripedium parviflorum*.—This Lady's-slipper seems to be less particular as to soil and cultivation than the other hardy *Cypripediums*. It thrives here and increases under conditions which suit *Lily-of-the-valley*. It is slightly shaded by a deciduous tree and in soil rather inclined to stiffness.

Elizabeth, N. J.

J. N. G.

*Physalis Franchetti*.—To those who tried this fine new species last summer it was a disappointment. It was regarded as a pot-plant, and at first even seemed an annual. Late in summer it seemed that stolons were being formed for the next year's display, and we left outdoors those that had been planted out to see if they would prove hardy. These plants are now growing freely in the open border. It is evidently a good hardy perennial in habit, and by no means fitted for pot-culture, for the plants that were carried over winter in pots have not been as satisfactory as the ones in the border. This plant has been extensively advertised as the new Chinese Lantern-plant. It was one of the discoveries of Mr. James Veitch during his visit to Japan, or, at least, to him we are indebted for living plants.

*Cypripedium bellatulum*.—Some notes of this beautiful *Cypripede* were published recently in these columns, more espe-

cially as to its culture, and it is not necessary now to say more on this point. A specimen recently exhibited before the Massachusetts Horticultural Society deserves special mention, both for its beauty and its high culture. This plant bore ten fully expanded flowers of large size, the pot being comparatively small for the number of flowers. It was thought deserving of the silver medal of the society. Mr. James E. Rothwell, of Brookline, who is the possessor of this plant, has many fine specimens of this species. One is gigantic in habit of growth and size of flower, the leaves being nearly a foot long and very broad. Another variety is unique in that the spots are in distinct lines through the middle of each segment of the flower. It is a pleasure to find the requirements of these plants so well understood, and they are only one of the remarkable examples of high culture to be seen in this interesting collection which promises soon to become famous. I was pleased to see here a fine specimen of the pure white variety of *C. bellatulum*. This is the easiest to grow, perhaps, of all its kindred. The leaves themselves are devoid of all purple markings, and it is a very rare plant. Only one, so far as we can learn, has been introduced, but owing to its easy culture it should not long remain unattainable.

South Lancaster, Mass.

E. O. Orpet.

**The Protection of Roses in Winter.**—Mr. Bradley's notes on Protecting Roses in Winter (see page 209) are well worthy of attention. Almost every one who has had the care of plants in winter knows that darkness or shade is half the battle in their preservation. I have seen such plants as *Pittosporums*, *Oranges*, *Lemons*, *Hydrangea hortensia* and *Figs* pass through a winter safely in an open shed, free from sunlight. Last winter, when placing some *Arbor-vitæ* branches about a *Magnolia grandiflora*, I left one branch on the northern side outside the covering purposely, to see what the effect would be. But little sun reached it late in the afternoon. It came through until spring with trifling damage, the leaves being slightly browned here and there, but no more than those inside the *Arbor-vitæ* covering. Shade from the sun is what partly tender plants want in winter.

Germantown, Pa.

Joseph Meehan.

## Correspondence.

### Nurseries at South Orange, New Jersey.

To the Editor of GARDEN AND FOREST:

Sir,—Mr. W. A. Manda, who bought a few acres of wild land in the beautiful Orange Valley, at South Orange Station, only two years ago, in so short a time has brought order out of chaos, and in this "Universal Horticultural Establishment" has a large representation of most of the good things in cultivation, and a great many valuable and novel plants not often seen. As South Orange happens to be within my cycling circuit my visits here are frequent, and to me one of the most striking characteristics of the place is the rapid change, as different plants and features of interest succeed each other. Last fall, I remember, there were five thousand or more fine seedling *Araucarias*, which is not an ordinary sight. Later the frames were filled with Roman *Hyacinths*, frozen up for Easter, and last week tiny *Heaths*, which seem to strike here as readily as *Geraniums*, could be counted by the thousand. But Mr. Manda's special pride was spring-flowering *Lælias*, *L. elegans* and *L. purpurea*, of which he claims to possess the best collection in the country. Certainly there was a wonderful variety of coloring among the three hundred plants, and they were in fine vigor and of all sizes, from those with a single break to one with a dozen or more, bearing sixty-six noble flowers, richly colored, and including probably all the rare kinds which appeal, aside from any beauty, to collectors. Mr. Manda has been fortunate in his houses, for *Orchids* of all sorts grow thriftily there, as I have before taken occasion to note, and there seems to be a rapidly increasing assortment of these valuable plants. Last year Mr. Manda discarded benches in his main Palm-house with a gratifying effect, and the plants set out seem much more vigorous. In the outdoor nursery there was, as usual, a large assortment of seasonable hardy plants in flower, with a great breadth of *Pæonies* just showing color. One of the most striking novelties is a variegated form of *Lilium longiflorum*. This has a distinct white margin on each leaf and is otherwise like the type in hardiness and flower. Mr. Manda is an admirer of Japanese plants, and is at work on a Japanese garden—probably without the stones and sentiment. He certainly has managed to get together, besides a great lot of Tree *Pæonies*, *Irises*, *Maples*, etc., a curious and interesting collection of odd things, ranging from Ferns to Oaks. There is also a wonderful collection of varie-

gated plants, mostly of a shrubby character, which will interest those who care to punctuate their gardens. The gem of the Japanese collection is a white form of the short-clustered *Wistaria*, *W. brachybotrys alba*, which is probably new to cultivation here. This forms a woody stem three to five feet high, with numerous pendent branches, which, in the middle of May, are covered with short racemes of pure white flowers. It is evidently a choice shrub for the lawn or for growing in a pot for special decoration.

Elizabeth, N. J.

J. N. Gerard.

## Exhibitions.

### The Boston Flower Show.

OWING to the mildness of the past winter and a favorable spring, flowers of *Rhododendron* exhibited in Horticultural Hall, Boston, Massachusetts, last week, were finer than any ever seen here before. The exhibits in every instance were large, and the capacity of the hall was taxed so much that several important shipments were unopened.

The tender varieties attracted most attention. The collection of H. H. Hunnewell, Esq., was uncommonly good. Among the choice kinds were Duchess of Sutherland, rosy, with deeper color on the edge; Mrs. Jackeye, blush, and spotted like a *Pelargonium*; Sir Jos. Whitworth, very dark purple, large flowers; Sigismund Kucker, red rose, dark centre; Mrs. R. G. Shaw, blush tinted, red-spotted standard; Lady Grey Edgerton, rosy, with yellow spots; Mr. H. H. Hunnewell, deep rose, with dark standard. The tender varieties from the F. B. Hayes' estate, exhibited by Mr. James Comley, included *Onslowianum*, blush, orange spots; Princess Mary of Cambridge, extra fine, rosy, with lighter centre; Lady Clarence Cathcart, warm rose, red spots; John Walters, rosy red; Duchess of Edinboro, white centre, red on the edge; Dorothy Neville, blush, dark standard.

A new variety, Mrs. Powers Wilson, exhibited by Mr. Comley, attracted much attention. The trusses were extra large, color blush, with *pelargonium*-like spots on the standard.

Mrs. B. P. Cheney had a large exhibit of fine hardy sorts. Mrs. J. L. Gardener and Dr. Weld had specially good collections. Wm. Nicholson, of Framingham, showed a splendid vase of *Carnations*. Mr. Clinkaberry, gardener to C. G. Roebling, Esq., Trenton, New Jersey, made a grand showing of *Orchids*, including many rare and beautiful varieties of *Lælia purpurata*. Among these were *Russelliana*, delicately veined with purple, and *Roeblingiana*, marbled with pink and veined. *Lælio-Cattleya*, var. C. G. Roebling, is of the *L. purpurata* type, with golden throat. *Cattleya Warneriana*, var. *lilacina*, is a lovely shade of rose with a white band at the throat. *Cypripedium Chamberlainianum* is curious as well as beautiful. There is a distinct stem with small leaves arranged distichously; the flowers occur on short stems in the axils of the leaves. Green and purple are curiously blended throughout the flower; the pouch is of a deeper purplish shade. Flowers of *Cypripedium caudatum* had tails nearly two feet long.

N. T. Kidder, Esq., had a beautiful lot of show *Pelargoniums*, which, unfortunately, for want of space, had to be arranged on the steps in poor light. Kenneth Findlayson, gardener to Dr. Weld, showed *Iris Susiana* in flower.

Wild flowers proved interesting to a larger number of people than would be expected, and the collections contained almost the entire list of the interesting wild flowers in bloom near Boston at the present time.

## Recent Publications.

*Flowers of Field, Hill and Swamp*. By Caroline A. Creevey. Illustrated by Benjamin Lander. New York: Harper & Brothers. 1897.

This beautifully printed volume of 550 pages is another attempt to help novices to call the common plants he meets by their botanical names. That Mrs. Creevey does not always adhere to one system of nomenclature is a matter of minor importance in a book of this sort, which does not pretend to have any such high scientific purpose as to engage in one or another side of the various controversies now ranging over the proper method of naming plants. Still it is rather confusing for the student who wishes to verify his work by examining some other book to find that the names used by Mrs. Creevey are not all in any one manual. The feature in which the book is especially strong is the popular descriptions of the plants and

of their ways and habits. These show a keen observation and marked literary skill. When, for example, she characterizes Bouncing Bet as "a slovenly flower with a backyardish appearance," we are apprehensive that association may have led her to be a trifle unjust, even though the phrase is picturesque. But one more phrase justifies the whole, "the calyx bursts and the petals seem tumbling out of place." The botanical descriptions proper are not as good as the popular ones. The author is not successful in selecting the distinguishing characteristics either of species or of genera, and left to these descriptions alone the student would find small assistance in the book. The figures are much better than those usually found in similar books. They are not always drawn to bring out the marked specific qualities of a plant, but they represent with much force and spirit the general air of the plant, and they show the true artistic touch.

The novelty in the book is in its arrangement. Within a few years there have been books in which the plants have been grouped according to their structural affinities, the colors of their flowers and the times in which they bloom; while this one is an attempt to bring plants into classes according to their usual place of growth, and it is certain, as Mrs. Creevey holds in her introduction, that a classification of plants upon the natural basis of their environment, including shade, soil, moisture, etc., has certain advantages. It is really a part of botanical education to know the plants which grow near the sea-coast, those which grow in bogs and marshes, on the borders of brooks, in wet meadows or dry fields, in rocky woods or open sandy soil. The environment of a plant accounts for a great many of its ways and habits, and the grouping of many plants together which are subjected to the same influences ought to lead the careful student to the discovery of many interesting facts in biology. On the other hand, this arrangement is an unfortunate one for the beginner, and this book is made exclusively for beginners. Many plants are rather cosmopolitan in their habits, and it will not be strange if the student should discover on a sandy hillside some plant which is classified in Mrs. Creevey's book as a wood plant or marsh plant because it is nearly always found there. We have in mind a spot in a rather moist meadow where the little stars of *Houstonia* bloom every spring, but this plant is grouped, and very properly so, among those which thrive in dry fields and waste places. Again, to any one who has regard for system, the tendency to group plants according to their generic and family likenesses is irresistible. It is rather disheartening to find the various species of one genus scattered all through the book, and in many cases with nothing like a generic description, or when there is an attempt at this a very meagre and unsatisfactory one. We cannot help feeling that the book would have been more useful if the plants had been arranged in the text according to their families, with one or two of Mr. Lander's fine drawings for each important genus. The central purpose of the book could then have been carried out by lists of plants arranged according to their habitat. After all, structural resemblance is the true basis of classification, interesting as classification by environment may be. It is not true, as Mrs. Creevey says, that a plant born to wet soil will not flourish on dry. Our beautiful Cardinal-flower, which, by the way, is most felicitously described by her, although always born in or near the water, will flourish in any ordinary garden soil, and so will the Marsh Mallow and the Swamp Maple. We notice a few inaccuracies of statement, as, for example, that the Golden-rod cannot be cultivated, but, as a rule, the text can be trusted as correct, and every reader will at once be attracted by the sprightliness of the style.

## Notes

The twenty-eighth season of the New York Flower and Fruit Mission is now begun, and flowers and delicacies for the sick are received on Monday and Thursday mornings of each week

at the rooms of the society. Those who have country gardens may give pleasure and refreshment to the patients in hospitals and tenements by sending flowers, fruits, vegetables, jellies, eggs and other suitable articles of food. And those who have no products of country garden or kitchen to give, and who live in the city or near-by and spend some part of the summer at home, can help the work effectively in making up the flowers into small bouquets and in distributing the gifts. It may be well to say again that the express companies carry donations for this work free of charge, and particulars as to packing, etc., may be had on application by mail to the secretary at 104 East Twentieth Street, this city.

The first Burbank plums, from Florida, are now in our markets, but so early in the season are more showy than luscious. They cost twenty-five cents a dozen. Bidwell peaches, from the same state, fully grown and ripe, cost seventy-five cents for a basket holding thirty fruits. Bright Royal Ann cherries and other choice varieties, from California, cost thirty to thirty-five cents a pound, and apricots of fair size sell for thirty cents a dozen. Cherries and strawberries are now coming from the Hudson River district of this state, and the latter can be had of good size and quality for ten cents a quart box. Large, regularly formed and deep, evenly colored strawberries, known as the Gem, from Hilton, New Jersey, cost twenty cents a quart, and a fancy variety, Mary, from the same section, sells for forty cents. These berries are of immense size, many of them seven to eight inches around, but they are flattened and lack the ideal form of the Gem. Other small fruits now fairly matured are huckleberries and blackberries, both of which sell for twenty cents a quart.

People who have been raising cucumbers for market near New York have found a great decrease in the productiveness of the later plantings, the crop of which has been used as pickles, while the early vines which produce cucumbers sold in the market have not been affected. The cause of the loss is the downy mildew, a fungous disease which does not appear to any alarming extent until late July, and then it spreads quickly over the fields. The older leaves are first attacked near the centre of the vine, and then the disease spreads outwardly. The flowers are produced, but no cucumbers set, or, if they do, they grow slowly and become misshapen and unmarketable. Insect ravages usually spread from the borders of the field inward, and the wilt disease shows a sudden drooping of the leaves. The disease in question is allied to the downy mildew of the grape, and the fungus lives upon many cucurbitaceous plants. The Bordeaux mixture, used at intervals of a week or ten days, has proved a convenient, inexpensive and a sure preventive.

One of the great obstacles in using liquids to destroy insects and fungi is the difficulty of obtaining pumps of sufficient power. Professor Maynard, in the report of the Hatch Experiment Station, asserts that a steam spraying outfit will do better and cheaper work than hand or gear machines. Of course, the manipulator must know the construction of his engine and pump and have skill to keep the parts in working order. The cost of these outfits ranges from \$200 to \$400, which is too great for the small farmer or fruit grower, but in almost every village or town the work of spraying for many persons by a single owner could be done at a less cost than if each person equipped himself with small and imperfectly working pumps. It would be more satisfactory than if the plant were owned by a number of individuals, and, of course, the steam engine, fitted with a fly-wheel, could be used not only for spraying, but for cutting wood, corn-fodder or ensilage, grinding grain, pumping water, and, in short, it might be made a source of profit in many directions.

Professor Massey writes from the Experiment Station at Raleigh, North Carolina, that he picked Snead peaches, dead ripe and soft, on the 5th of June, and no other early peach is colored yet. The Snead is larger than most of the extra-early peaches, and is a fine-looking fruit, although lacking high color. It has the usual fault of its class, and gets soft on the outside, while remaining hard and adherent within. The Greensboro Peach, which was very promising last year, will fruit at the station this year. It is not ripe, but will probably come in with the Amsden and Alexander, and it is a much larger peach. Professor Massey adds that Blackberries are going north now in quantity. Most of the growers in North Carolina adhere to the Wilson, but in many places there is the same trouble that has driven this variety out of cultivation in other places—that is, the making of double flowers. Early Harvest is fine, and has an enormous crop, but where the

Wilson does well its size will always sell it in competition with the Early Harvest for more money. He has found nothing in Blackberries better than these two. The experimental fruit plats, covering seventy-five acres at Southern Pines, are beginning to make a fine show. These are not variety tests, but a study of the effects of different combinations of plant-food on nearly absolutely barren sand.

Last week marked the largest receipts of pineapples which may be expected here this season. The first cutting of this fruit in the Bahamas is usually made between the 20th of May and the 1st of June, so that the heavy shipments from these islands and from Cuba and Florida last week amounted to many hundred thousand fruits. One schooner of ninety tons burden brought 75,000 pineapples to this port, another schooner brought 115,000, and there were besides five other schooners and as many steamers loaded with the fruit. The season practically ends early in July, although there will be smaller quantities coming from Florida during August and September. The Florida fruit has superior keeping qualities and better flavor, and can be successfully forwarded to the far western states. It comes in crates of uniform size containing twenty-four, thirty or thirty-six of the fruits, larger or smaller, and sells at wholesale to the dealer who retails it for \$2.75 to \$3.75 a crate, or at from eight to sixteen cents each. The Bahama pineapples come in bulk, and are sold at \$5.00 to \$6.00 a hundred in lots of a thousand. Those from Cuba, sixty to one hundred in a barrel, sell for \$3.50 to \$5.50 a barrel. All the fruit now coming from the Bahamas is of the kind known as Strawberry, and most of that coming from Cuba is of the same sort, only a couple of hundred barrels of the Sugar-loaf variety having arrived last week. From Florida many kinds are now received, as Queen, Red Spanish, Porto Rico, etc. The latter cost from forty to seventy-five cents apiece in large quantities. The abundance of this wholesome fruit makes low prices for the consumer, and the Bahama or Cuba product may be had for ten to fifteen cents by the retail buyer, and the higher grades and larger sizes at prices advancing to \$1.00 each.

Robert Douglas, for many years a conspicuous figure among the arboriculturists of this country, died suddenly at his home in Waukegan, Illinois, on June 2d. He was born at Gateshead, near Halifax, England, in 1813, and went to Canada in 1836. In 1838 he removed to Whitingham, Vermont, where he kept the county-inn for a short time, but in 1844 he set out for the west and drove through the then sparsely inhabited country and established his home, about thirty miles north of Chicago, on the shores of Lake Michigan, at the place which has since become the town of Waukegan. Here he resumed the trade of tailor, learned years before, but in 1848, impelled by a strong love of nature which had declared itself in his boyhood, when he lived with his parents in Fallon's nursery, near Newcastle, he established a small nursery business. A year later, when the California gold fever broke out, Mr. Douglas set out with a party of his neighbors to cross the continent. In fording the Bear River, among the Wahsatch Mountains, he lost his team, and, impatient of the slow progress of the emigrant train, with characteristic courage he set out alone and crossed the deserts of Utah and Nevada and the Sierra Nevada, on foot. He remained in California but a short time, and returned to Waukegan to take up his nursery work. He was the first man to grow forest-tree seedlings by the million, and for nearly half a century he devoted his time and skill to raising conifer and other tree seedlings. He planted large forests in many western states, and the most successful plantations of *Catalpa speciosa* in the United States were made by him near Farlington, in Kansas. His counsel has always been in demand wherever forest problems were studied in this country, as, for example, at the Leland Stanford University, in California, and George W. Vanderbilt's estate at Biltmore, North Carolina. He was one of the valued assistants of Professor Sargent in gathering data for his forest report of the Tenth Census, and many of the specimens in the Jesup collection of woods in the Museum of Natural History, in this city, were collected by him. No one in his time has devoted himself to the study of trees with greater intelligence or success, and no one has done more to increase the love for them or to encourage the planting of them in the United States. Mr. Douglas was endowed with a hardy constitution, and his faculties were in full vigor almost until the hour of his death, in his eighty-fifth year. The total lack of self-seeking in his nature, his unfailing cheerfulness and rich sense of humor, made him one of the most agreeable of companions, and the integrity and purity of his life commanded the respect and affection of all who knew him.

Doing Too Much.

MORE than once in these pages attention has been drawn to one of the chief mistakes of those who own or design country places in America. This is the mistake of doing too much. The art of gardening design, whether practiced upon a large or a small scale, is based upon nature in a very literal sense. The painter and the sculptor must base their art upon nature in so far that they must aim to reproduce her effects. But the artist in landscape is under closer obligations than this. He cannot choose a blank canvas and reproduce any natural effect that he happens to desire. Usually the outlines and main features of his picture are already indicated by nature. And even if he finds a piece of ground which is wholly devoid of irregularities in surface and of native vegetation, the proper method of treating it is suggested by its surroundings and outlook, by the character of the exposure, the climate and the soil, and by that of the vegetation to which these have given birth upon neighboring areas.

Of course, such a case as this is more uninteresting, more discouraging than any other. Diversities of level and natural growths of trees, shrubs and flowers are highly prized by the landscape artist. They make his task more grateful, not merely because they furnish features which could not be artificially produced at once, but also because they indicate the special as well as the general character of the effect which will be appropriate upon the given site. The true artist carefully preserves nature's preliminary provisions when he begins his work, accepts them as the nucleus of his design, and adds nothing which is inharmonious and nothing which is in excess of the actual artistic requirements of the case. On the other hand, the inartistic gardener or owner does not accept nature's scheme and loyally adhere to it. He fails to see that it is a scheme—a true design, if only, perhaps, in outline and suggestion. He confuses her intentions and spoils her suggested result by disregarding the characteristics of the site in placing his buildings and paths, by adding plants which do not harmonize with the indigenous vegetation, and, in nine cases out of ten, by using far too many of them and thus creating a disorderly medley instead of a rational composition.

This is what is usually meant when one speaks of "doing too much" in the treatment of a country place. But something even worse than this is done in certain instances by the owners of American country sites—something which cannot be seen or read about without exciting the utmost surprise in the mind of any one who believes that our fellow-countrymen are possessed of the common sense which may not mean real artistic aptitude, but is absolutely essential as its basis. In certain instances nature's handiwork is altogether swept away before the gardener is asked to begin his work. This is doing too much, indeed. Of course, even on the site most beautifully furnished by nature, the artist is privileged to eliminate, no less than to add, as art may dictate. But to eliminate everything in advance of his advent is an act of vandalism and of purest folly. It is to spoil nature, and at the same time to deprive art of its chance to create beauty of any individual or effective kind.

Every one knows, for example, that the surroundings of the city of Chicago are for the most part flat and featureless, that the soil is poor and the vegetation scant and scrubby. And every one should know that it must be difficult in such localities to create country places, villa sites, or those villages of houses each surrounded by its own small grounds, which are characteristic of the suburbs of our great western towns. For some miles to the northward of Chicago the suburbs are, indeed, of a flat and monotonous character most discouraging to the artist. Even here, however, beauty of an orderly, quiet, modest kind can be secured, as is shown by the streets near the borders of Graceland Cemetery. And those who know what the site of the newer part of this cemetery was less than twenty years ago, and who have seen that it is to-day one of the most attractive rural burial grounds in America, understand the radical transformations which can be produced by an artist as intelligent and skillful as its creator, Mr. Simonds.

Nevertheless, it might be supposed that, in such a region as this, all places to which nature has actually given a degree of individuality and charm would be highly valued, and their peculiarities sedulously preserved. Such is not the case. As one drives, for example, along the lake shore between the villages near Graceland and the more distant one called Winnetka, the surface becomes more diversified and the vegetation increases in size and variety until, at Winnetka, a cross-range of hills ends on the shore in a rolling expanse of country forming bluffs from thirty to fifty feet in height at certain points. Larger trees than one finds elsewhere now abound, chiefly Cottonwoods and Oaks; narrow but steep and rugged ravines are interspersed with tracts of forest of much charm and picturesque-ness; and in the more open parts thickets and clumps of beautiful shrubs cover the soil, Thorns, Crab-apples, Sumachs and Willows preponderating.

On the edge of the highest of these ridges, with a beautiful outlook over the lake, stands a house the grounds of which have been carefully treated by Mr. Simonds. He has done enough to make them fitting accompaniments for a human habitation of some dignity, yet not too much either in the way of addition or of elimination. The site for the house was chosen with his assistance, and, therefore, its foundation fits the irregularities of the spot; and the trees and shrubs which nature had planted grow up around its walls in as friendly and harmonious a manner as though man had set them out after the walls were built. The sloping ground over which one looks toward the lake still bears its natural crop of Sumachs, Thorns and Crab-apples, beautiful at all seasons, and enchanting when they are loaded with blossoms, while the turf about them has been improved. And on the entrance side of the house the approach winds under Oak-trees which long have held their station, and amid groups of native shrubs increased in number, but not altered in general character and effect by harmonious plantings. This house was built less than two years ago, but it has been so well adapted to the natural

character of its site that it looks as thoroughly at home as though it had stood for thirty years; and the peculiar charm of its surroundings springs from their peculiarly local character. Nowhere else but just here on the shore of Lake Michigan could they wear the aspect they wear to-day; and only a very ignorant eye would be willing to change their individual beauty for that of a more gardenesque or more conventional kind.

Another instance of the intelligent treatment of a peculiar site is found near Graceland, in the Saddle and Cycle Clubhouse and its grounds. The low sandy bluffs overhanging the beach have not been leveled or changed for the support of this house. It stretches itself picturesquely along the verge of two of them, the little break between being spanned by a graceful arch, which carries a connecting piazza. A natural grove of Oaks comfortably overshadows its roofs, and the native vegetation has not been disturbed by uprootings or by the addition of inharmonious plants. This house also looks as though it had grown where it stands, and its effect is both beautiful and individual, because nature's scheme has been understood and respected. But not far away runs a straight road bordered on both sides by villas, one row of them immediately facing the lake. Here we see very clearly the effects of the evil art of doing too much. The process by which many of the little places have been given an empty, conventional, unindividual, unattractive aspect is revealed by the many lots upon which no houses yet stand. Those which have not yet been "improved" are diversified in surface—not boldly, but to a degree which would afford an intelligent artist a chance to individualize each lot by the placing of the house and its paths and outbuildings. They are covered with picturesque groves of trees, wind-blown and rugged, yet for this very reason harmonizing admirably with the outlook over the beach and the wind-swept lake. And they are furthermore adorned by rich undergrowths of large shrubs and luxuriant vines. Adjacent lots, however, show the process of "improvement" which will rapidly sweep all these features away. The lots which are called ready for purchaser and builder have been carefully reduced to an absolute level; all the trees, except, perhaps, one or two of the largest, have been removed, and every trace of shrubs, flowers and natural turf has been wiped away. These lots resemble huge garden-beds prepared for the work of "bedding out." They are utterly ruined as characteristic sites in a locality to which nature had given a peculiar sort of beauty; and, swept by the cold breath of Lake Michigan, they are unfit for the production of conventional gardenesque effects. The only thing that an artist could wish to do with them would be to restore such irregularities of surface as they once displayed and to reproduce the sort of vegetation with which they once were clothed. This, of course, would be a difficult, if not an impossible, process, and would demand many years for its fulfillment. Practically, the sites are destroyed for all artistic purposes.

There are many places in this section where similar offenses against good taste are evident, and many persons who are considered intelligent and cultivated seem to think that all trees are ugly and intrusive, and all shrubs and flowers offensive weeds, unless they are counted in the gardener's list of ornamental plants. If these ideas and their expression in practice were confined to one district it would be hardly worth while to criticise them. Unfortunately, however, in one or another form they are revealed to the traveler in almost every part of our land. Many planters have never learned that to produce artistic results upon nature's canvas one must follow her suggestions and use her local materials. The evil art of doing too much afflicts the mind and eye both in indiscreet additions to nature's work and indiscreet preparatory eliminations of this work.

There is harmony in planting as there is in music. Variety and even wildness may be admitted, but discord cannot be allowed.—*Planting and Rural Ornament.* 1796.

### *Pinus muricata.*

FOUR species of the Pine-trees of the United States grow by the sea on the Pacific coast, maintaining a foothold in the most exposed situations and tossing their sturdy branches to the gale. The first of these, *Pinus contorta*, stretches along the coast from Alaska to Mendocino County, California. This is a small tree, rarely more than thirty feet high, and on the white clay barrens of Mendocino, ripening miniature cones when only a few inches in height. This tree, however, is not confined to the immediate neighborhood of the coast, but spreads inland through Alaska, British Columbia, Washington and Oregon, and, assuming various forms, ultimately passes into the Lodge Pole Pine of both slopes of the Rocky Mountains and of the high California Sierras.

From a point just north of the southern limits of the range of *Pinus contorta*, the second of these maritime Pines, *Pinus muricata*, stretches southward along the California coast, leaving several gaps, however, as far south at least as San Luis Obispo County, and reappears on the coast of Lower California.

*Pinus muricata* is one of the Pines which produce their leaves in pairs and is a tree usually from twenty-five to fifty feet in height, although much larger individuals may sometimes be seen, especially toward the northern limits of its range, where it grows apparently much larger than farther south. This Pine has little value economically, as the wood is too resinous and coarse-grained for any use except as fuel, and as an ornamental tree in cultivation it has little to recommend it, although on the inland side of low hills back from Tomalis Point, north of San Francisco Bay, it becomes sometimes a handsome round-topped, symmetrical tree with a dense head of dark foliage. It is chiefly interesting from the remarkable thickness of the bark, which on comparatively small trunks is sometimes five or six inches thick, a peculiarity which is well shown in our illustration on page 235 of this issue, made from a photograph for which we are indebted to Mr. J. G. Lemmon, the enthusiastic and successful student of the conifers of western North America. It is also remarkable for the persistence of its ovate oblique cones, armed with short, stout, recurved prickles, which are produced in whorls and remain on the trunk and branches sometimes for thirty or forty years, often becoming imbedded in the bark.

The third of these trees, *Pinus radiata*, or, as it is more generally known, *Pinus insignis*, is more restricted in its distribution, being confined to the region immediately adjacent to the Bay of Monterey, where it forms a narrow forest a few miles long back of the grove of Monterey Cypresses on Point Pinos. It is this Pine that surrounds and shelters the hotel Del Monte at Monterey.

The fourth of these Pines, *Pinus Torreyana*, is found only on the border of the high bluff and on the sides of the ravines extending from it to the sea, north and south of Del Mar, in San Diego County, where it stretches along the coast for a distance of nearly eight miles, but nowhere penetrates inland more than a mile and a half. A single grove of this tree also grows on the east end of Santa Rosa Island, off the California coast.

### Private Forestry and State Forestry.—I.

FOR years both Congress and the state legislatures throughout the country have anticipated the disastrous effects of the disappearance of the forests. But, unfortunately, as soon as the question, What is to be done? is raised, we find among the legislators as many opinions as there are members, because on account of lack of experience it is impossible to decide in advance what is the best scheme. Inaction on the ground of ignorance of the best method shows poor statesmanship. Von Moltke used to say, "To act unwisely is wiser than not to act at all," and this certainly holds good with forestry. Whatever the beginning in forestry may be—if there is only a decided

beginning all over the country—true forestry will develop and progress be made.

But what is true forestry? In Germany and France true forest management was formerly considered to be the making use of the forests without diminishing the growing stock, the quantity of wood and timber cut and removed from the various parts of the forest during a year or a period of years being kept equal to the increment over the entire forest area.\*

Experience in this country as well as abroad has shown that private landowners are likely to slaughter their forests in order to gain quick returns with larger immediate profits. If the father does not act thus, his son or his grandson assuredly will. Few men are so rich as not to feel the need of ready money once in a while; and few are so constant in resolution as not to take capital out of one business in order to invest it in another, when there is a prospect of larger immediate profits. Now, it is easy enough to take capital out of a forest-clad area; but it is difficult to put it back—that is, to restore the forest growth. Rarely will a landowner enjoy so long a life as to be able to fell trees of his own planting. And even were it otherwise, few people care to invest money in a venture which will make no return for scores of years, accumulating interest in such a manner that dividends cannot be separated from the original capital—a venture which is constantly endangered by fire and lawlessness, and which constantly swallows up money in the shape of taxes. Thus, well-stocked forests owned by private individuals are sure to be cut over more rapidly than they are reproduced; and poorly stocked forests, or areas deprived of their forest covers, when owned by private individuals, will scarcely ever be improved or planted anew.

However, forests may continue to exist even in the hands of private individuals with proper laws. This is the case in Austria, Switzerland, France and Germany. In the last-named country about one-half of the forest area is owned by private individuals. A large number of the owners, however, are not allowed to dispose of their forests, the property being entailed. In these cases the family is, in fact, the owner of the forest estate, and one or more members of it, carefully watched by the eyes of the law and by the other members of the family, enjoy the benefit of using the products of the forest within the limits of its productiveness. They are not allowed to cut more than its normal growth—that is, its annual increment. It has happened repeatedly that a family has brought suit against the member in possession, charging him with overcutting the forests. History has taught that entailed forest property admits of a proper and even a conservative forest management.

Owners of woodland in the Old Country who are independent of their families, as a rule, own but small areas, on an average certainly not more than a hundred acres. On forest lands of this extent forest management to furnish annual returns is scarcely feasible, and here again human nature would lead to the ruin of the forest if not checked by strictly enforced laws. Of course, owners cannot be hindered from cutting their crops as soon as they deem them ripe for the axe; more than that, they are even allowed to remove the litter from the ground, thus exhausting gradually the productiveness of the land. But they are prevented from changing woodland into farm or pasture; they are compelled after a clear cutting to plant the area within a few years; they are obliged to share pro area in the payment of a forest guard, whose duty it is to protect the forest from theft, from fire and from damage by cattle, game and insects; and the laws of inheritance do not admit of the splitting up of woodlands into fragments smaller than, say, two acres. It goes without saying that all private owners of woodland have been and are opposed to such measures and laws. The revolution of 1848 in Baden was an outburst of this opposition. Even to-day no European legis-

lature is without an organized opposition to the heavy burden of the forest laws. The great majority of the voters, however, realize the necessity for such measures—the necessity of restraining individuals or classes with a view to the protection and benefit of the people as a whole. In short, history has proved for Europe that private forests cannot be maintained in proper condition and productiveness unless they are either entailed or administered under strict legal restraint.

In this country the principle of individual freedom will long prevent the passing of laws similar to the forest laws of Europe. Entailed forest property is still an impossibility. Thus, we might be led to believe that the American forests are hopelessly lost to true forestry, but they are not. The definition of the term "true forest management" given above, as stated, was formerly the ruling one. Since 1870, however, a bold opposition has arisen which puts the financial or economic side of forestry to the front. The economic definition reads: "True forest management is that which yields the greatest money returns." In fact, since 1870, German and French foresters have become Americanized. They have more or less abandoned the vexation of leaving large amounts of capital, bearing a low interest, invested in the production of timber trees. Generally speaking, forests should be cut at the time when their annual increment (increase of value of stumpage) no longer affords an adequate interest on the capital which the stumpage represents. The truth of this principle of forestry is leading at the present moment to a considerable reduction of the growing stock of trees in Germany, Austria, Switzerland and France. Of course, this reduction cannot be carried through at once, for that would overstock the European market with lumber. However, the forester's aim is to have that amount of capital, and that amount only, invested in the forests which will yield the highest interest on the capital invested. If, for instance, a growing stock worth \$200,000 allows of an annual net revenue of \$6,000, while with the growing stock reduced to a value of \$100,000 the yield would be \$4,000 annually, the gradual reduction would be considered advisable. The entire matter is so plain and simple that one might be at a loss to understand why this main principle of forestry was scarcely discovered before 1870, and is not yet recognized by many European foresters. It would lead me too far to explain this fact at length.

There are some considerations, however, which diminish the influence of this principle on general practice. The financial principle neglects altogether the fact of the indirect utility of the forests in their influence upon temperature, water-supply, health, etc. Neither does it take into consideration the duty of the state to provide for the timber-supply and lumber industry of the next generation. In other words, it does not hold as good with state forestry as it does with private forestry. Furthermore, the financial principle is greatly influenced by circumstances which are hardly capable of economic expression. Such are fluctuations in the value of stumpage and lumber, possible legislation affecting the customs or dealing with reforestation or forest fires, the constant decrease of interest on capital all over the world, going hand in hand with an increase in civilization, and a legion of similar considerations.

Biltmore, N. C.

C. A. Schenck.

### The California Orchards.

THE fruit crop of California is again below the average, owing to frosts in some districts and to hot dry winds in others. A few valleys report larger crops than usual, and single orchards are in some cases well laden, though surrounded by others that have no fruit. The following notes are from personal observation and the reports of correspondents:

Almonds are much below the average, but in a few districts show a large crop. Apricots are generally excellent, except in Sacramento, Kern and parts of Ventura counties.

\* Bulletin No. 5 of the United States Division of Forestry, entitled "What is Forestry?"

Cherries are below the average, particularly the large, light-colored varieties, such as Royal Ann. Peaches are difficult to report upon, because districts vary so greatly, but the crop is thought to be only an average one. Pears, Plums and Prunes promise a fair crop in a few places, but seem to be short in many orchards. Los Gatos, San Benito and Solano districts report the prune crop as from one-third to one-half of the average season. The pears, also, have fallen badly. In fact, it is too early to determine exactly the prospects for either pears or prunes. Apples seem to be in good condition. Walnuts are up to the average. The grape crop, so far as reported, is better than usual.

In most cases under my own observations, more injury was done by the failure of late rains and by the hot days of early April than by frosts. But in the parts of the state subject to frosts there has been much injury to deciduous fruit-trees from "sour-sap," which, as Professor Woodworth, of the University of California, recently explained, consists in the fermentation of the sap of the plant by apparently the same organisms that cause the souring of milk. Root sour-sap occurs after very wet winters, in badly drained soil, and the smaller roots rot away. Sour-sap in the trunk and branches of trees occurs when late frosts, after warm days, rupture the growing cells, so that decay organisms find entrance. One orchard association has reported the loss of a thousand large trees from this sour-sap.

Taking a general view of the fruit industry of California, as should be occasionally done so as to prevent people from making unprofitable investments, the outlook is not very encouraging except in a few limited directions. Of course, reports of large profits made by persons engaged in fruit growing still continue, but at present they should be believed only after careful judgment. The average orchardist has not made any money to speak of for three seasons past, and some of the leading men in the business have become bankrupt. Some orchards have been cut down and many have been regrafted. This is particularly true of Almonds, which have been grafted over to Prunes.

There is now a general feeling in California that the fruit industry ought not to have much, if any, expansion for several years to come. Perhaps one fruit grower in a hundred will find orchard extension profitable, but nearly all will lessen their area and specialize their products.

The wiser residents regret to see sales of colony lands at high prices to non-residents for orchards which must be planned, planted and cared for by agents or by those who sold the land. California offers many and great inducements to persons who are able to buy land, live on it, and begin work there, supporting themselves by plain, old-fashioned, mixed farming until they have learned how to specialize. And this kind of pioneering, of growing up with the country, appears needful to later contentment.

One colony in this state boasts that it has more than a hundred non-resident investors, most of whom will not see the land they own until it is covered with bearing vines and trees. For five or six years they have paid for the planting and care, hoping to find their orchards and vineyards profitable. But such tracts, managed by syndicates and associations, have never been satisfactory, even from a financial standpoint, while the poor installment-payers are without that homely attachment to trees that one has planted, and to gardens that one has created, which is really the only salvation. Thousands of acres of these alien and hireling orchards are likely to go back to pasture and wheat fields.

Niles, Calif.

## Foreign Correspondence.

### London Letter.

THE annual exhibition of the Royal Horticultural Society was held this week in the Temple Gardens, and, notwithstanding somewhat unfavorable weather, it was an unqualified success. The exhibits were, on the whole, of superior quality to those of previous years, while

the company was greater. Her Royal Highness the Princess of Wales visited the exhibition on the opening day and expressed her delight with it.

ORCHIDS.—The collections sent by Sir Trevor Lawrence, Baron Schroeder, Mr. W. S. Ellis, and by Messrs. Sander & Co., Low & Co., B. S. Williams & Son, Cypher, Lewis & Co., Charlesworth & Co., and Messrs. Linden, of Brussels, were remarkable for their extent and excellence, both as to specimens and variety. The enormous plant of *Cœlogyne Dayand*, bearing twenty-four racemes of flowers a yard long, was a feature for about the fourth time, proving that good cultivation alone, and not, as was at first suggested, imported vigor was the cause of its flowering so freely. The rare *Cypripedium callosum Sanderæ*, bearing two flowers, *Bulbophyllum barbegirum* with two spikes, *Hexisia bidentata*, a charming *Dendrobium*-like plant with scarlet flowers, *Lælio-Cattleya Digbyana-Mossiaë*, a big specimen of that most delightful of *Dendrobes*, *D. Loddigisii* (*pulchellum*), a group of well-flowered specimens of *Vanda teres*, and, of course, numerous choice varieties of *Odontoglossum crispum*, were among the most attractive of the plants in Baron Schroeder's group. Sir Trevor Lawrence always sends many Orchids of botanical interest, and in this respect this year was no exception. Passing over the big and perfect specimens of *Cattleya*, *Dendrobium*, *Cypripedium* and *Odontoglossum*, we may note the pan of *Neottia Nidus-avis* with its brown flowers, *Trichocaulon longibracteatum* with white flowers stained with crimson on the front and side lobes of the lip, *Dendrobium Auguste-Victoria* with tall pseudo-bulbs and spikes in the way of *D. stratiotis*, *D. signatum aureum* with flowers of pale sulphur-yellow color, in form like those of *D. lituiflorum*, *Eria ornata* with a long hairy scape of large yellow-brown bracts and green flowers with orange lip, *Epidendrum Mooreanum*, a rather new species in the way of *E. virens*, with crimson blotches on the lip of the greenish yellow flowers, *Lycaste jugosa*, *Microstylis macrocheila* and a grand plant of the tiger-flowered *Maxillaria Sanderiana*.

Messrs. F. Sander & Co. were, as usual, liberal exhibitors. A large plant of *Cattleya Reineckiana*, bearing thirteen flowers and buds, was shown; also a new hybrid called *Lælio-Cattleya the Queen*, *Cattleya Rossii*, raised from *C. intermedia* and *C. Leopoldii*, bearing three spikes and eighteen flowers, which were like those of *intermedia*, but spotted and tinted as in *Leopoldii*. *Dendrobium Dalhousieanum* was represented by large specimens carrying dozens of spikes of its large yellow and crimson flowers, and *Anæctochilus Sanderianus*, one of the most charming of the genus, *Sobralia Veitchii* with large bluish-white flowers splashed with yellow in the throat, and *Stenoglottis longifolia*, and a pure white-flowered form of it revealed the charm of this pretty Cape terrestrial Orchid.

Messrs. H. Low & Co. sent some rare *Phalænopsis*, *Cœlogyne asperata*, *C. pandurata* and a beautiful form of *Odontoglossum crispum* named *Queen Victoria*, to which a first-class certificate was awarded. It has medium-sized flowers, rose-tinted, with a large crimson-brown blotch on each segment. Messrs. Linden's group consisted almost wholly of *Odontoglossum crispum* varieties and forms of *Cattleya Mossiaë*, the latter being superior to any that I have seen. They also sent a gigantic-flowered form of *C. Schilleriana*, to which a first-class certificate was awarded. The three choicest Orchids, sent by Messrs. Charlesworth, of Bradford, were *Sophro-Lælia Marriottiana*, raised from *S. grandiflora* and *L. flava*, *Lælio-Cattleya Lady Wigan*, to which a first-class certificate was awarded; it is a hybrid between *L. purpurata* and *C. Mossiaë*. The third plant was a beautiful variety of *Odontoglossum excelens* named *R. Ashworth*. The most admired Orchid exhibited was a form of *Odontoglossum crispum* named *Starlight*. It bore a spike of six flowers nearly four inches across, with broad sepals and petals colored rose-purple and peppered all over with red-brown. It was sent by Mr. Broman White, and was awarded a first-class certificate. Connoisseurs bracketed with this truly lovely plant

a hybrid of unknown parentage, but showing evidences of *Lælia purpurata* and *Cattleya aurea*. It bore the cumbrous name of *Lælio-Cattleya Lyntesfieldiense*. The sepals and petals were rosy mauve, and the broad, wavy lip deep maroon-crimson almost to the base. It obtained a first-class certificate.

*Luddemannia Lehmanni*, bearing three spikes of bloom ;

been seen finer, and the *Caladiums* from Messrs. Laing and Veitch were marvels of good culture as well as creditable to the breeders of these plants, which have been greatly improved in the last ten years. Among the *Carnations* I noted several of excellence—*Duchess Consuelo*, a yellow in the way of *Germania*, and raised by Mr. Willans, gardener to the Duke of Marlborough ; James O'Brien, a large, full,

Fig. 30.—*Pinus muricata* on the coast of California.—See page 232.

very large specimens of *Cypripedium caudatum*, *C. Chapmani magnificum* (*Curtisii* × *bellatulum*), and another hybrid between *C. bellatulum* and *C. concolor* were other Orchids of special interest.

The collections of *Roses*, *Caladiums*, *Carnations*, herbaceous plants, *Rhododendrons* and other hardy flowering shrubs were rich and full of interest. *Roses* have never

deep crimson flower, and *The Pasha*, a yellowish salmon variety, shown by Messrs. Cutbush.

*Crimson Rambler Rose* is as popular as ever, some well-flowered specimens occurring in several of the big groups. A *Tea Rose* named *Enchantress*, with large flowers in the way of *A. Ollivier*, but paler, is a promising variety which Mr. W. Paul raised about two years ago. Messrs. Sutton's

Gloxinias, Cannells' Begonias, Cannas, Calceolarias and Gloxinias, Balchin's Boronias, Heaths, Phœnocomas and other hard-wooded plants, May's Ferns, Kelway's Pyrethrums, Iris, Aquilegias, Pæonies, Dobbie's Pansies and single Dahlias, Veitch's Streptocarpus and Phyllocactus, Wallace's Lilies, Iris, Calochortus and Brodiaeas, Jackman's hybrid Clematis, and Smith & Co.'s giant specimens of the popular large-flowered sorts, are collections which may be mentioned as having contributed largely to the success of the exhibition.

**NEW PLANTS.**—Messrs. Veitch showed a very large-flowered variety of *Hydrangea hortensis*, the barren flowers over two inches across and of a rich rose color. Messrs. Sander & Co. showed their new *Dracunas* and *Caladiums*, a variegated *Canna*, *Mapania pandanifolia*, two *Petunias* and *Davallia hirta*. Mr. Bull showed a form of *Ficus radicans* with silvery variegated leaves; he also showed his new *Anemia rotundifolia*, with long, narrow, pinnate, arched fronds, and *Crinum Moorei* variegatum. Monsieur Moser, of Marseilles, sent a new *Clematis* with large flowers, the petals pale rose, banded with cerise.

The number of new plants exhibited this year was exceptionally small. It is said to be due to the forthcoming Ghent Quinquennial Exhibition next year, at which one of the great features is always new plants, and for which the nurserymen appear to be holding themselves in reserve.

London.

## Cultural Department.

### The Asparagus Rust Again.

THE season of 1896 was the first one in which the genuine rust of the *Asparagus*, *Puccinia asparagi*, had been observed in this country, at least in the eastern states, and in quantity to make its presence alarming. During the autumn months the *Asparagus* fields, instead of being a luxuriant green, turned to a brown, which suggested the ravages of an insect or the work of an untimely frost. Early in autumn the surface of the infested *Asparagus* stems was more or less covered with patches or pustules of an orange color, due to the myriads of spores that had formed in minute rifts and ruptures of the epidermis. Later on, in the fall, the same spots upon the stems became dark-colored, a brown form of spore having replaced the brighter one. In this condition the story of the outbreak and life history of the fungus closed for 1896.

This microscopic parasite has long been known in Europe, and has three forms, at least, in which it thrives upon the *Asparagus*. The brown pustules of late autumn, the stage in which the fungus passes the winter, are followed the next season by a form very different from either of the two previously mentioned. This is commonly known as the "cluster cup" stage, and consists, so far as the eye sees, of minute cup-shaped bodies which arise from the infested stem in small groups or clusters, hence the common name for this form of the rust fungi. This cluster cup form was to be expected as the beginning of the attack of the rust for the present year, and it appeared during the past week. On the third of June, samples of the cluster cup fungus were sent to me from the centre of a large area devoted to the cultivation of *Asparagus*. The cutting of the crop is at its height, and the rust is confined to young plants that are allowed to grow to gain strength for future years. The first rust was found upon the plants that grew in a vineyard that had been in *Asparagus* some years before. These were vigorous shoots that came from roots that had not been killed out. The clusters of cups are most frequently found upon the main stem and a foot or so above the ground, while not infrequently they appear close to the soil, and even the fine branches at the top of the plant are sometimes rusted.

An examination of young beds set this spring showed that these plants were bearing the fungus cups, and the beds of last year's setting were in like manner infested. The stems in old beds that are being cut from day to day do not stand long enough for the fungus to show itself, but after cutting ceases there is reasonable certainty that these beds will also show the first form of the rust, and be followed by the second and third stages of the fungus before the season closes.

It is too early to know the results that will follow the treatment recommended last autumn, namely, the cutting and

burning of the rusted plants. One thing is already certain and that is the great falling off of the yield. From reports received upon this point from various growers, and those in charge of shipments at the centres of *Asparagus* growing, it is gathered that the yield is not more than half that of the ordinary season. This may be due in small part to cool weather, but there is sufficient ground for attributing it largely to the rust, which was overwhelming in its attack last season. It is also learned that there is no material difference in the yield upon fields where the brush was cut and burned and where it was left standing through the winter. The effect of the burning upon the amount of rust later in the season will be looked for with much interest.

Growers of *Asparagus* are anxious to know what to do now in view of the fact that the first form of the rust is in sight. All *Asparagus* that is "growing wild" should be destroyed, as it is a propagating place for the rust. Spraying should be resorted to as soon as cutting is through and shoots begin to form for the season's work of assimilation. The Bordeaux mixture or some other standard fungicide may be applied at intervals of about ten days. The fungus is not in the group that has heretofore yielded promptly to this treatment, but there is hope of doing some good. The value of spraying with fungicides is being tested in the field of *Asparagus* upon the ground of the Experiment Station, and as soon as possible the results will be published.

New Jersey Experiment Station.

Byron D. Halsted.

### Climbing Plants for the Greenhouse.

EVERY greenhouse provides some corner in which a climber can be displayed to advantage, though in a house of limited area judgment must be exercised in the selection of plants for this purpose. Where abundant space can be allowed for such rampant growers, the *Tacsonias* and *Passifloras* are especially beautiful, and quite a moderate temperature is generally sufficient for their needs—that is, the temperature of an intermediate house, say, from fifty-five to sixty degrees. The most satisfactory method of cultivating is to plant out in well-drained beds and train the growth without too much formality along wires attached to the roof.

*Passiflora racemosa* is one of the most satisfactory of the *Passion-flowers*, and from its habit of blooming from both young and growing shoots and also from the old hard wood, a well-established plant is seldom without flowers. Cuttings of firm young wood will root at almost any time, but as plants raised in this manner do not always start away freely, *P. racemosa* is frequently grafted on *P. Raddiana* or some other free-growing species. In grafting, the stock frequently suckers freely, and this objectionable feature requires watching.

*Passiflora vitifolia*, sometimes called *Tacsonia Buchananii*, is also an admirable climber and grows rapidly. After it becomes somewhat root-bound it flowers profusely, the solitary flowers hanging on long pedicels below the foliage. *Tacsonia Van Volxemii* is another favorite for conservatory decoration, and, while a rapid grower, neither the foliage nor wood is so coarse as that of the *P. vitifolia*, and it is more graceful. The flowers of this *Tacsonia* swing on slender stems, usually more than a foot in length. They are rich crimson in color and four to five inches in diameter, and altogether showy and attractive.

*Tacsonia Exoniensis* is a hybrid variety introduced some twenty years ago and resembles in habit *T. Van Volxemii*, but the leaves are smoother and the flowers deep pink. *T. insignis* is another handsome species and is also free in growth. The flowers are large and dark crimson, but cuttings do not root quite as readily as those of the two preceding *Tacsonias*, and I think *T. insignis* is less prolific in flowers, at least until the plant becomes slightly starved.

The Butterfly Vine, *Stigmaphyllon ciliatum*, flourishes under conditions similar to those required for *Tacsonia*. It flowers freely during the summer months, when planted out-of-doors, from Washington, District of Columbia, southward. It is much smaller in leaf and finer in growth than the *Tacsonias*, and is therefore adapted for smaller houses. It requires bright sunlight and a light, rich soil.

*Thunbergia Harrisii*, another old favorite, is suited for commodious quarters. While the individual flowers do not last very long, they are produced in profusion, and their shade of blue is none too common. *T. Harrisii* stands close pruning, which is fortunate, for mealy bug often attacks the plants, and the annual pruning gives a clean start, and thus saves trouble later in the season. Cuttings two to three joints in length, from rather light wood, will root quickly in rich loam with free watering.

The beds for these strong-growing climbers should be built

of brick or concrete, about three by two feet and eighteen inches deep. The drainage should be thorough and the soil rich and rather coarse—that is, only broken up with a spade in mixing. For a fertilizer I prefer bone-dust in moderate quantity, with a good proportion of barnyard manure.

If a house sufficiently cool is available, *Lapageria rosea* and *L. alba* should not be omitted, but unless the necessary conditions of coolness and abundant ventilation can be given these beautiful plants will not thrive, and insect attacks are likely to follow.

*Stephanotis floribunda* and one or two of the *Tecomas* are useful, and do not require great heat, but *Stephanotis* is another favorite of mealy bug, and strong syringing with a good pressure of water is necessary to keep down this pest.

Of the *Tecomas*, *T. jasminoides* and *T. Smithii* can be safely recommended. The first is a strong grower, and does not bloom freely until it has grown to considerable size, while *T. Smithii* flowers while quite small, and is satisfactory either as a pot-plant or when planted out. *Trachelosperma jasminoides* is well adapted for growing on a trellis in a pot or tub, and gives an abundant crop of white Jasmine-like flowers. A rather peaty soil is preferable, and a temperature no higher than forty-five to fifty degrees.

For warm-house treatment few, if any, climbers surpass some of the *Dipladenias*. These can be handled to better advantage in pots than when planted out in a house, and experience has shown that it is not necessary to coddle these plants, as was once the practice.

Holmesburg, Pa.

W. H. Taplin.

### Hardy Rhododendrons.

RHODODENDRONS at Wellesley are exceptionally fine this season, owing to the mildness of the past winter and a favorable spring. The list of varieties once considered tender, and now regarded as hardy, is being gradually extended. New plantations not infrequently lose their first season's setting of buds, consequent upon insufficient root development. Even though all the conditions for successful cultivation are favorable, we should not decide as to hardiness after one, or even two years' testing. There has never been any doubt of the hardiness of hybrids in which the blood of our native *R. Catawbiense* prevails.

One must become interested enough in these plants to study somewhat the history of hybrid Rhododendrons in order to give them intelligent cultivation. We depend almost entirely upon European raisers, mostly English nurserymen, for our supply, and the consequence is many beautiful varieties, hardy enough in England, and recommended in good faith, have been imported, and proved altogether unsuitable to our climate. We find many of them injured beyond recovery after the first winter, while some linger on for a season or two. Loss of vitality, resulting from an ocean voyage and change of soil and climate must, of course, be allowed for. *R. Ponticum* is quite hardy in England, and is there considered the best parent for hybridizing and also as stock for grafting. While the good qualities of *R. Catawbiense* are recognized, and a plentiful infusion exists among standard sorts, it is, nevertheless, difficult to tell to what extent this is so. *R. arboreum*, the Himalayan species, and the tenderest of this type, is also used as a parent. It is from this species that we get the finely tinted rose, crimson and ruby-red shades so much desired. But in proportion as *R. arboreum* and *R. Ponticum* enter into the parentage of a hybrid, the less reliable is it for American cultivators, especially in this latitude.

When it is not possible to know the history of the varieties we wish to grow, we must trust to the recommendations of raisers and dealers who use our native species as a parent or stock. The Messrs. Waterer, of England, have made a specialty for many years of raising varieties for the American trade, and nearly all the finest varieties in our gardens have come from them. Many of the so-called tender varieties are conspicuous for the size of their individual flowers, the form and size of the truss, distinct colors and splendid markings. To establish, to acclimatize these has been slow work. The material at first was not the best. Large old plants which have been moved in and out of cover for a number of years, and which are likely to be out of health, are not the most favorable subjects to experiment with. As a rule, they take hold slowly, but the expected loss from winter cold has not proved serious. It does not appear so much a question of constitutional weakness as to get the flower-buds thoroughly matured and to find proper protection for them. There is generally a good setting of buds, but without flowers the most ardent enthusiast is apt to lose courage. The plants screened from the irritating effects of bright sunshine during winter suffer least, and on this

suggestion most experiments have been carried out with satisfactory results, and so every year varieties are taken from the doubtful list and counted as hardy. Frequent examinations throughout the winter show that during the severest weather the buds kept sound, and not until the sharp changes from low night temperature to bright, often warm, days in March and early April does the real injury occur. Plants sheltered from the north and exposed to the full sun suffer most.

A list of choice varieties not generally found to be hardy in this neighborhood, and which have been out several winters and are now in fine condition, includes *Duchess of Sutherland*, rosy lilac, deeper margin; *Princess Mary of Cambridge*, blush, edged with carmine; *F. D. Godman*, crimson, large dark standard petal, fine foliage; *James Mackintosh*, rosy scarlet, fine truss; *Marshall Brooks*, rich scarlet, with bronze spots, distinct and beautiful; *John Walter*, rich crimson, fine form, very effective; *Charles Thorold*, purple, bronze standard, fine habit and good foliage; *Mrs. C. Thorold*, bright pink, yellow centre, distinct and beautiful; *Mrs. Shuttleworth*, scarlet, lighter centre, spotted, very attractive; *Lady Rolle*, white, spotted; *Mrs. Heywood*, bright rose, free; *Countess of Normanton*, blush-white, dark spotted, showy; *Mrs. J. P. Lade*, French gray, deeper centre, fine truss.

Among a large number of varieties reliable as to hardiness the following are noteworthy for fine colors, large flowers and handsome trusses: *Lady Armstrong*, rosy spotted, early; *Caractacus*, deep crimson, one of the best for all purposes; *Mrs. John Clutton*, splendid white, standard petal spotted yellow; *Mrs. C. S. Sargent*, rosy, marked with yellow, handsome foliage; *E. S. Rand*, rich scarlet; *Setton*, purple, large flowers, late; *Lady Crossley*, deep rose, distinct, early; *Queen*, blush, nicely marked, with yellow spots, requires shade; *Lady Grey Egerton*, silvery rose, large truss, handsome; *Mr. H. H. Hunnewell*, deep rose, bold truss; *Charles Bagley*, cherry red; *Mrs. Henry S. Hunnewell*, very fine white, will prove our best white; *King of the Purples*, striking color; *Album elegans*, blush, changing to white; *Album grandiflorum*, white; *Delicatissimum*, valuable on account of being late and associated with a mass of *Kalmia latifolia*, comes into bloom at the same time; *Ralph Sanders*, rich purplish crimson; *F. L. Ames*, probably the most striking of any of the rosy-flowered varieties, the flowers very large, truss well built, color blush, with deeper edge. Mum would be my choice among nearly two hundred varieties. It is white, with creamy spots on the standard petal, the flowers are extra large and the truss superbly formed, but it is doubtfully hardy. Plants which have been out for two years are blooming sparsely this spring, and it is hoped when better established it may prove entirely hardy.

Wellesley, Mass.

T. D. Hatfield.

### The Cultivation of *Dionæa*.

IT is seldom this wonderful little plant is seen in a good state of cultivation any length of time after removal from its native haunts. Its cultivation in a greenhouse is usually attended with more or less difficulty, owing to unsuitable conditions, such as too much dry air, shade or unfriendly soil. It delights in full sunshine with a very humid atmosphere. When the plants can be secured and transplanted with considerable of the soil in which they grow attached to the bulb-like root-stock they are quite easily dealt with, and may be kept in a healthy growing state for years. I find a round, hanging earthenware receptacle most useful to grow them in; the bottom is carefully drained, first with large pieces of broken pots, then smaller pieces, and the upper layer is quite fine. Some chopped fibrous peat is placed above this, when the plants are built in, with live sphagnum moss used to fill the spaces between the clumps. Arranged in this way, it is hardly possible to give them too much water, and they revel in abundant supplies. If kept in the sun the leaves take on a reddish tinge, but when grown in the shade they are always green. Flowers will develop about this time, but they should be nipped off as they make their appearance, for they are apt to weaken the plant.

The *Dionæa* has been grown successfully in a dwelling-house by quite a different method. The plants were in a wide shallow dish without any drainage, and simply placed, not too firmly, in loose live sphagnum moss, with a glass covering. Water was given every other day by filling the space above the plants until the dish was filled, and then it was poured off. In this way the potting material never became sour. From the luxuriant condition in which these plants remained for years, I am inclined to think this to have been a close imitation of the conditions under which they thrive in a wild state. Some years ago, owing to Professor Asa Gray's endeavor to

have the Government purchase a strip of land on which this plant grows, there existed a widespread idea that it was gradually becoming extinct. There seems to be little likelihood of this calamity, however, as *Dionæa* is found abundantly in some places all the way from Wilmington to Fayetteville, in North Carolina. Its permanency is all the more assured seeing that the plants thrive on soil which is of little use for agricultural purposes.

Botanic Garden, Washington, D. C.

G. W. Oliver.

### June Irises.

EARLY in June, just as the bloom of hybrid German Irises is waning, we may expect the flowers of another group scarcely less interesting and with colors as bright as those of any of the family. These Spanish Irises are bulbous and natives of south-western Europe and northern Africa. While there are several species and numerous hybrids in the group varying somewhat in hardiness, those which are classed by the Dutch bulb growers as Spanish Irises are all perfectly hardy in this latitude with no protection. They are yellow, blue, blue-purple and white, selfs and in combination, and sometimes with an admixture of brown. The Spanish Irises have narrow leaves which spear in early winter, and they flower at about eighteen inches in height. There are three forms in general cultivation; those with narrow falls spreading laterally are the most common; the Portuguese yellow form, *I. Lusitanica*, has relatively broad falls which rise slantingly, and there is a vigorous old form known as *The Thunderbolt*, with bronzy flowers, which is larger in all its parts. As most of these Irises may be had at a low price they should be planted in large groups, when they are most effective, and in the open, where they will receive the full benefit of spring rains, or if these are lacking they require generous waterings. A full supply of water in the spring is necessary to their successful growth and flowering, even if they have been well matured the previous summer. They have flowered particularly well this wet season, and some neglected bulbs which seldom flower, owing to too dry a location, have been brought forward by the abundant recent rains.

Some of the bulbous Irises are scarce even at a high price, and too many dealers fill orders for these with Spanish Irises, always at high prices. Having been at the losing end of such transactions a number of times, I offer the suggestion that consignments of bulbs should be compared with one's stock of bulbs of Spanish Irises and those of the same form under different names should be regarded with some reserve.

**Asparagus Sprengeri.**—This can no longer be considered a new plant, for it is well distributed over the continent now, and those who were fortunate enough to secure plants early are beginning to enjoy the results of their venture, for the purchase of new plants is speculation of the purest kind. Not only do the plants sometimes vary from the published descriptions, but their behavior is sometimes extremely local, a fault the vender is not to be held responsible for. I am told that in Italy, where Mr. Sprenger had the original plants growing, the stems were upward of eight feet high and studded over with brilliant scarlet seeds, and the visitor who was my informant was most enthusiastic over the plant. *Asparagus Sprengeri* promises to be even more durable when cut than either of the other kinds now so commonly grown, and though it will never supplant *A. plumosus* and *A. tenuissimus* in public favor, it will make a sure place for itself. Our largest plant is now in a twelve-inch pot, and cultivators will find that unlimited pot-room is essential for its success, or it must be planted out. The tubers are so numerous that they soon push the soil up out of the pot. The new potting material, Jaddoo fibre, is said to be best suited for such plants. It affords free root-room and enables the tubers to expand in the pots. The flowers of *A. Sprengeri* are quite pretty, being pure white on short racemes, and the anthers are of a bright orange color. It is decidedly ornamental when in bloom, and one can easily understand the effect of the red berries when ripe. The plant must be propagated from seeds; cuttings will not root, as with *A. tenuissimus*. Seeds must be freely obtainable, to judge from the rapidity of its distribution recently.

**Ranunculus Ficaria.**—This is an interesting Buttercup which appears to have made its way to America now for the first time. It was found growing as a weed in a pot with some imported greenhouse plants about two years ago, and is now well established in a small way in one or two Buffalo gardens. It much resembles the *Caltha* and blossoms even earlier, so that

it will be valuable in the list of April bloomers. The leaves are less than half the size of those of the *Caltha* and run from round heart-shape into broadly halberd-shape or sagittate; they are smooth, growing in a cluster that entirely conceals the short stems, from which the numerous scape-like golden-yellow flowers rise. The peculiarity which distinguishes it from allied plants is the production of numerous elongated, whitish tubers of the size of small peas. These are readily separated some distance from the parent plant, and the plants that spring from them also bear tubers before they are large enough to blossom. The plant disappears after maturing its tubers, not waiting to bear seed, but is perennial and reappears the next season. This *Ranunculus* was known to Linnæus, who appears to have found it under the common name of *Ficaria*, the fig plant, and incorporated the name into its scientific title, as he so often did in other instances.

### A Garden of Roses.

To the Editor of GARDEN AND FOREST:

Sir,—In reference to Mr. Gerard's article on garden Roses, on page 217 of GARDEN AND FOREST, I must put in a plea for the so-called Hybrid Perpetuals, because of their splendid decorative effects in the June garden. It is true that their blooming season is soon past, but that is equally true of all shrubs and flowering trees, and of most herbaceous plants as well. We would hardly miss any other flowers so much as these. Their flowers are so large and showy, and so freely produced, and the plants grow to so much larger size than the Teas that I think them preëminently desirable in any garden where there is space enough to admit of their full development. Their foliage is beautiful, and the new growth has fine coloring, so that with their graceful habit of growth when allowed to develop naturally they are attractive throughout the summer after the flowering season is past. Besides, they do give flowers occasionally in late summer and in the fall. As I write there is before me a garden of Roses in their prime, consisting entirely of June Roses and Hybrid Perpetuals. Here Ulrich Brunner forms a large bush with a hundred perfect roses of a rich, dark, velvety red. *R. multiflora* has taken possession of a Mulberry-tree, over which it rambles and which it has clothed with a beautiful garment of shining, healthy foliage and masses of pure white clustered flowers. In this lovely wilderness Paul Neyron is trained to a stake twelve feet high, and from this elevation its immense roses overlook all their neighbors. Abel Carrière has a little trellis to support it, not too stiffly, and is covered with its beautiful crimson blooms. Giant of Battles was one of the first to open here, long before a Tea Rose had shown its color. It is ten feet in height, the main stem tied to a stake from which many wand-like branches depend, blooming in beautiful profusion. Old-fashioned double white Roses, such as *Microphylla*, *Coquette des Alpes* and *Madame Plantier* blend with the deep red flowers I have named, and the queen of them all is *Madame Alfred Carrière*, which needs an arbor to itself on which to display the flushed blossoms with their exquisite fragrance.

In this old garden most of the Roses are old, and there are many Hundred-leaved Roses and Rose of Provence, Burnet, Damask, Moss and Cinnamon Roses in waste places and rock-brakes, growing as they will. The well-ordered beds of Teas, beautiful as they are, seem small and tame by comparison. Hybrid Perpetuals increase in beauty every year, and this is seldom true of the Teas, which must be often replanted. But almost every type of Rose is beautiful and desirable, and the Rose lover is likely to find room in his heart and in his garden for all.
